## Acknowledgments

First, I would like to thank Prof. Dr. Irina Druzhinina for giving me the opportunity to conduct my master thesis in her research group Microbiology and Applied Genomics and for her feedback in every step of this project.

Second, I would like to thank DI Komal Chenthamara for her constant support and encouragement, especially for giving me directions and help in crucial moments of my master thesis.

I would also like to thank all members of the Research Group Microbiology and Applied Genomics for a pleasant work atmosphere and time spent together.

Last but not least I would like to thank my friends and family for their unconditional love and support.

## Abstract

The comparative genomics study of the industrially relevant *Trichoderma* spp. (Hypocreales, Ascomycota) revealed a considerable expansion of ankyrin-domain-containing- (ANKdc-) proteins when compared to other ecologically similar Pezizomycotina fungi. Ankyrin-(ANK-) domains are found in all domains of life as the only identifiable structural motif or as associates of other PFAM (host) domains that may be involved in a diversity of functions such as signal transduction, transport, transcription regulation, inflammatory response and other essential cell processes. The role of ANKdc-proteins in fungi remains poorly understood. In this thesis, a comprehensive *in silico* analysis of *Trichoderma* ANKYrome was performed to uncover the role of expansion of ANKdc-proteins in the ecology of *Trichoderma* spp. and provide the first hypotheses into their role in *Trichoderma* interactomes. A comparative genomics approach was used for genome mining, annotation, enumeration and classification of proteins with ANK-repeats in 10 *Trichoderma* species. In total, eighteen Hypocreales genomes were mined for ANKdc-proteins and 2406 of these proteins were retrieved. Our study revealed that the expansion of ANKdc-proteins is not exclusive to *Trichoderma*, but also evident in closely related fungi such as phytopathogenic Nectriaceae and Bionectriaceae. Indication that expansion of ANKdc is characteristic of phytopathogens as well, compels to look at more transcriptomic data of *Trichoderma* when interacting with plants or growing in soil to understand the role of ANKdc-proteins. By orthology inference, 1172 homologous ANKdc-proteins were distributed between 183 orthogroups of which 18 orthologous ANKdc-proteins were identified as core in *Trichoderma* spp. and 11 as core in all of 18 considered Hypocreales fungi. Thus, the results indicate that the larger share of ANKdc-proteins is unique to most species (orphans). All ANK-repeats in *Trichoderma* ANKYrome were annotated by InterProScan within Blast2GO using three databases, Pfam, SMART, and Prosite. Additionally, all host-domains were annotated within *Trichoderma* ANKYrome using the same approach but with all 14 databases available in InterProScan. This study revealed that two most frequent host-domains in *Trichoderma* ANKYrome are P-loop containing nucleoside triphosphate hydrolase and nucleoside phosphorylase, but also that majority of these ANKdc-proteins are orphan proteins. As nucleoside phosphorylases are known to play a role in immune responses, these results allow us to hypothesize that abundance of ANK-repeats in *Trichoderma* might be contributing to general fitness of this genus. Furthermore, SignalP and TMHMM analyses revealed that only a small share of *Trichoderma* ANKYrome consists of proteins involved in cell signaling or

transmembrane proteins, respectively. Evolutionary analyses of the core *Trichoderma* ANKyrome were performed using vertical evolution and purifying selection acting across each of 18 core ANKdc-proteins from *Trichoderma* spp.

## Kurzfassung

Die komparative genomische Studie der industriell relevanten Pilze *Trichoderma* spp. (Hypocreales, Ascomycota) zeigte eine beträchtliche Expansion von Ankyrin-Domäne-enthaltenden- (ANKdc-) Proteinen im Vergleich zu anderen ökologisch ähnlichen Pezizomycotina-Pilzen. Ankyrin- (ANK-) Domäne finden sich in allen Domänen des Lebens als das einzige identifizierbare Strukturmotif oder assoziiert mit anderen PFAM (host) Domänen, die an einer Vielfalt von Funktionen wie Signaltransduktion, Transport, Transkriptionsregulation, Entzündungsantwort und anderen essentiellen Zellprozessen beteiligt sein können. Die Rolle von ANKdc-Proteinen in Pilzen ist noch weitgehend ungeklärt. In dieser Arbeit wurde eine umfassende *in silico* Analyse der *Trichoderma* ANKYrome durchgeführt, um die Rolle der Expansion von ANKdc-Proteinen in der Ökologie von *Trichoderma* spp. zu erforschen und die ersten Hypothesen über ihre Rolle in *Trichoderma* Interaktomen zu stellen. Ein komparativer genomischer Ansatz wurde für Genom-Mining, Annotierung, Verzeichnis und Klassifizierung von Proteinen mit ANK-Repeats in zehn *Trichoderma*-Arten verwendet. Insgesamt wurden 18 Hypocreales-Genome nach ANKdc-Proteinen durchsucht und 2406 dieser Proteine gefunden. Unsere Studie zeigte, dass die Expansion von ANKdc-Proteinen nicht ausschließlich bei *Trichoderma* auftritt, sondern auch bei nahe verwandten Pilzen wie phytopathogenen Nectriaceae und Bionectriaceae.

Der Hinweis, dass die Expansion von ANKdc auch für Phytopathogene charakteristisch ist, zwingt dazu, mehr transkriptomische Daten von *Trichoderma* zu betrachten, wenn sie mit Pflanzen interagieren oder im Boden wachsen, um die Rolle von ANKdc-Proteinen zu verstehen. Durch Orthologie-Inferenz wurden 1172 homologe ANKdc-Proteine auf 183 Orthogruppen verteilt, von denen 18 orthologe ANKdc-Proteine als Core-Proteine in *Trichoderma* spp identifiziert wurden und 11 als Core-Proteine in allen der 18 betrachteten Hypocreales-Pilzen.

Somit zeigen die Ergebnisse, dass der größere Anteil an ANKdc-Proteinen für die meisten Arten einzigartig ist (Orphan). Alle ANK-Repeats in *Trichoderma* ANKYromen wurden annotiert durch InterProScan in Blast2GO mit drei Datenbanken, Pfam, SMART und Prosite. Darüber hinaus wurden alle Host-Domänen in *Trichoderma* ANKYromen mit dem gleichen Ansatz, aber mit allen 14 Datenbanken in InterProScan annotiert. Diese Studie ergab, dass die beiden häufigsten Host-Domänen in *Trichoderma* ANKYromen P-Loop-haltige Nucleosidtriphosphat-Hydrolase und Nucleosidphosphorylase sind, aber auch, dass die Mehrheit dieser ANKdc-Proteine

Orphan-Proteine sind. Da bekannt ist, dass Nucleosidphosphorylasen eine Rolle bei Immunantworten spielen, erlauben diese Ergebnisse die Hypothese, dass die Häufigkeit von ANK-Repeats in *Trichoderma* zur allgemeinen Fitness dieser Gattung beitragen könnte. SignalP- und TMHMM-Analysen zeigten, dass nur ein kleiner Teil vom *Trichoderma* ANKyrom aus Proteinen die an der Zellsignalisierung beteiligt sind bzw. Transmembranproteinen besteht. Evolutionäre Analysen des Core-ANKyrom von *Trichoderma* wurden durchgeführt unter der Verwendung von vertikaler Evolution und reinigender Selektion, die in jedem der 18 Core-Proteine in *Trichoderma* spp. wirkt.

# 1. Introduction

## 1.1 *Trichoderma* and their neighbors

Species of *Trichoderma* are filamentous Ascomycota found all over the world occupying vastly different ecological habitats, which is why many of them are often referred to as cosmopolitan and opportunistic organisms (Druzhinina *et al.* 2011; Gupta *et al.* 2014).

Taxonomically, *Trichoderma* belongs to the order of Hypocreales and the class of Sordaryomycetes. *Trichoderma* spp. are haploid organisms, but most also possess a functional heterothallic mode of sexual reproduction system, that is possible only between two different mating type individuals, namely *mat1-1* and *mat1-2* mating locus types (bipolar heterothallism) (Seidl *et al.* 2009).

Some members of *Trichoderma* genus secrete large amounts of certain CAZymes and find their application mainly in biotechnology as cellulase and hemicellulase producers for the food and biofuel industries. The most studied species for this application and in general is the industrial cellulase producer *T. reesei* (see Druzhinina *et al.* 2016 for the references; Stricker, Mach, and De Graaff 2008; Seiboth, Ivanova, and Seidl-Seiboth 2011). For this reason, *T. reesei* was sequenced in 2008, becoming the first genome from this genus to be studied (Martinez *et al.* 2008).

Druzhinina *et al.* (2018) described the expansion of nutritional strategies adapted by *Trichoderma*. These species have developed multiple nutritional modes which enable them to occupy vastly different ecological niches like other fungi, plants, dead wood, soil etc. Their ability to parasitize and kill other fungi, called mycoparasitism, as well as their production of antifungal secondary metabolites is applied as a biocontrol against plant pathogenic fungi (Harman *et al.* 2004). Furthermore, some *Trichoderma* spp. are used for stimulation of plant growth as associates or endophytes of plants, contributing to resistance to plant stresses and diseases (Harman 2011). Although there are many advantages of *Trichoderma* spp. applications, there are studies showing certain *Trichoderma* spp. causing green mold disease on mushroom farms (Komoń-Zelazowska *et al.* 2007). More importantly, some *Trichoderma* spp. act as pathogens of immunocompromised patients, especially organ transplant recipients (Chouaki *et al.* 2002). Due to above reasons, the interest to study their genotypes resulted in availability of 15 different genomes of *Trichoderma* in 2018. However, only 10 *Trichoderma* genomes were publicly available at the time of beginning of this master thesis.

In 2011, Kubicek *et al.* sequenced strongly opportunistic and cosmopolitan *T. atroviride* and *T. virens* and performed the first comparative genomics study with already published *T. reesei* genome (Kubicek *et al.* 2011). Inspired by this study, a more extensive Markov cluster algorithm (MCL) analysis of 44 Pezizomycotina genomes in total, including the three previously mentioned *Trichoderma* spp. was done (Irina Druzhinina, personal communication). The MCL analysis revealed that *Trichoderma* spp. contained an increased number of ankyrin-domain-containing (ANKdc) proteins compared to the average number of these genes in considered Pezizomycotina species (Figure 1). Furthermore, within *Trichoderma* genus, in strongly opportunistic and cosmopolitan *T. atroviride* and *T. virens*, ANKdc-proteins were even more expanded than in *T. reesei*. With this thesis, we aim to set foundation towards explaining the expansion and roles of ANKdc genes. Therefore, we selected genomes of *Trichoderma* and other closely related species for a comparative genomics study of their ANKdc-protein.

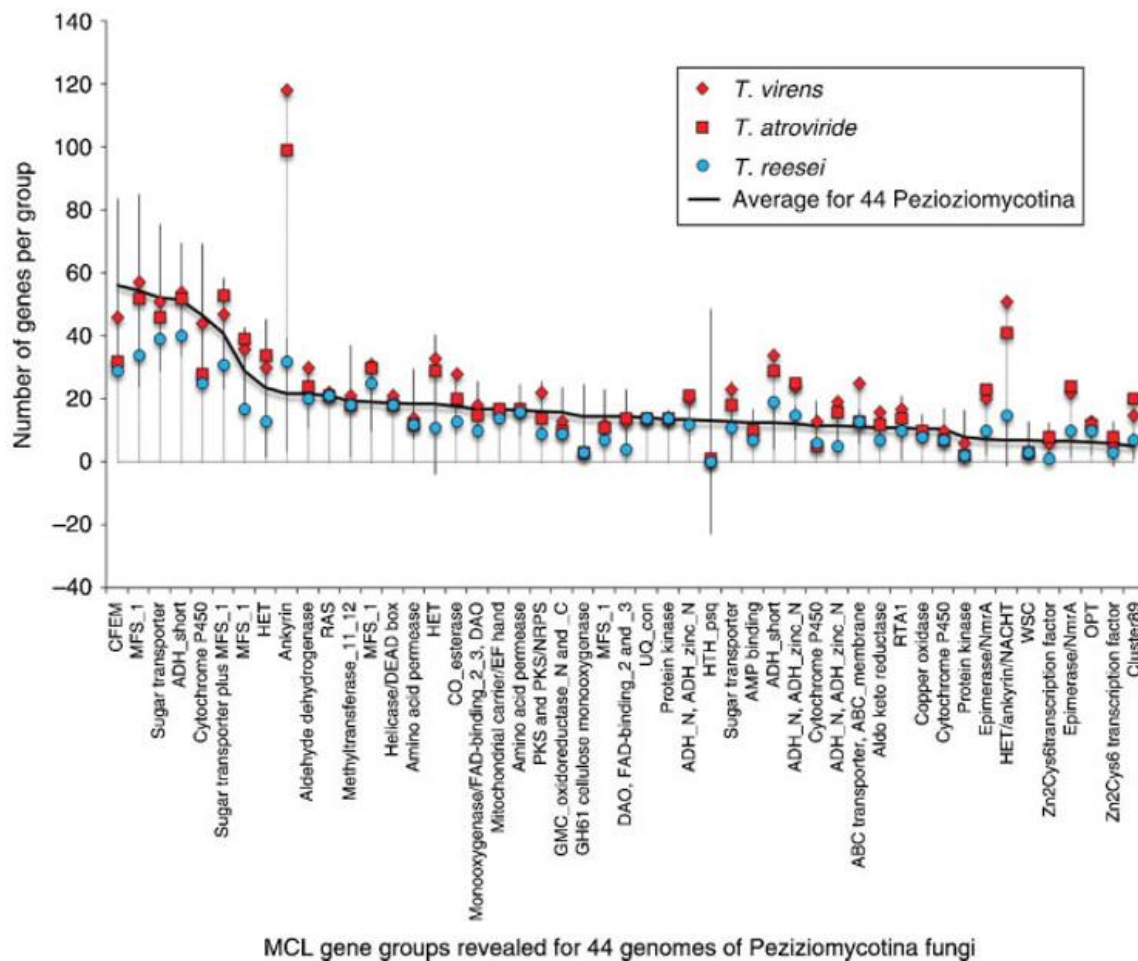

Figure 1: MCL analysis of gene families in 44 Pezizomycotina genomes. Irina Druzhinina, unpublished

Druzhinina *et al.* (2018) performed a multilocus phylogenetic analysis with 100 housekeeping genes from 21 Hypocreales genomes and two species from Sordariales order (Figure 2; adapted from Druzhinina *et al.* 2018), revealing the close neighbors of *Trichoderma*. This phylogenetic analysis confirmed the assumed classification of *Trichoderma* spp. into taxonomical sections *Longibrachiatum*, *Harzianum*, *Virens* and *Trichoderma*. It is evident from the phylogram that species of the *Longibrachiatum* section are evolutionarily most derived, while the *Trichoderma* section is closest to the last common ancestor of all *Trichoderma* spp. Furthermore, *E. weberi* (de Man *et al.* 2016) shares the last common ancestor with *Trichoderma* genus and it is a specialized mycoparasite, reflecting the ancestral state of *Trichoderma* spp. Moreover, it was revealed that *Trichoderma* spp. are closer to entomopathogens (carnivory) than their plant-associated hosts (herbivory). Availability of these eight other Hypocrealean genomes and their well-studied ecology (Smith 2007; Roy *et al.* 2010; Xiao *et al.* 2012) make them interesting candidates for comparison with the genomes of *Trichoderma*, in order to reveal clues about ANKdc-proteins expansion in *Trichoderma*.

## 1.2 Ankyrin-domain-containing proteins

The ankyrin- (ANK-) repeat is a protein-protein interaction motif found in proteins in all living organisms (Figure 3, Chenthamara *et al.* unpublished). It was named after a cytoskeletal protein ankyrin which contains 22 copies of the ANK-repeat (Lux, John, and Bennett 1990).

Figure 3: A sunburst diagram showing distribution of ANKdc-proteins across all domains of life. The number next to species name is the respective number of ANKdc-proteins reported in the respective species. Chenthamara *et al.*; unpublished

A single ANK-repeat consists of 33-amino acid residues that form a motif of a helix-turn-helix-beta-hairpin/loop fold, which is shown in Figure 4A. The two helices are arranged in antiparallel fashion followed by a loop region that points outward at an approximately 90° angle, resembling a structure similar to letter L (Gorina and Pavletich 1996). Specific residues, often referred to as signature residues, are relatively conserved to keep the structural integrity of the motif. The positions 4-7 are usually occupied by T-P-L-H (Threonine-Proline-Leucine-Histidine) amino acids. Proline at 5th position is responsible for the L-shaped structure by forming the tight turn and initiating the first helix. Hydrogen bonding between the hydroxyl group of threonine and the imidazole ring of histidine contribute to the stability of ANK-domain. In positions 17-22, amino acids V/I-V-X-L/V-LL (Valin/Isoleucine-Valin-XX(hydrophilic)-Leucine/Valine-Leucine-Leucine) form the central part of the second alpha-helix and inter- and intra-hydrophobic networks to stabilize the whole ANK-domain (Mosavi, Minor, and Peng 2002; Li, Mahajan, and Tsai 2006). Solvent accessibility affects the amino acid composition, so those residues that do not come into contact with solvent are usually hydrophobic and constitute the hydrophobic core of the ANK-domain. Some of these residues are replaced with hydrophilic residues in terminal ANK-repeats of an ANK-domain-containing (ANKdc)-protein because the solvent has access to them.

In ANK-domains, helices of one ANK-repeat pack against the helices of the adjacent ANK-repeat while the beta-hairpin/loop region, in some cases, forms a continuous beta-sheet as shown in Figure 4B. The tips of beta-hairpins/loop region and the surface of packed helices facing them are responsible for binding of the target molecule. The residues constituting these regions of ANK-domain are generally variable to ensure functional and binding specificity (Sedgwick and Smerdon 1999). On average there are 4-7 ANK-repeats per ANKdc-protein, and proteins with more ANK-repeats generally have more compact and concave structure which reflects their modular nature and enables their wide functional diversity (Mosavi *et al.* 2004).

The ANKdc-proteins can be loner-proteins, containing exclusively ANK-domain(s), or they can be multidomain proteins where ANK-domain(s) are associated with a functional (host) domain. These functional domains are involved in transcription regulation, signal transduction, cell-cell signaling, cell-cycle regulation, inflammatory response, cytoskeleton integrity, toxin-encoding, transport phenomena etc. (Bork 1993; Mosavi *et al.* 2004). The function of ANKdc-proteins in *Trichoderma* and fungi, in general, is not well understood.

Figure 4A and 4B: Conserved structural features of the ANK-repeat and ANKdc-proteins with high-resolution structures in the PDB. Al-Khodor & Souhaila, et al., 2010

## 2 Aims of the study and hypothesis

The hypothesis of our study is that the overrepresentation of ANKdc-proteins in *Trichoderma* spp. is linked to the fitness and thereby to the environmental success of this genus. Therefore, the aim of this thesis is a comprehensive *in silico* inventory and evolutionary analysis of *Trichoderma* ANKyrome. To achieve this aim the following tasks should be completed:

- Building an inventory of all ANKdc-proteins from 10 *Trichoderma* spp. and eight closely related non-*Trichoderma* Hypocrealean genomes (NTHGs), referred to as Hypocrealean ANKyrome
- Re-annotation of ANK-repeats and other associated host-domains (where present) in Hypocrealean ANKyrome using InterProScan
- Domain architecture analysis
- Comparison of *Trichoderma* ANKyrome to other closely related Hypocreales.
- Orthology inferences within the Hypocrealean ANKyrome
- Phylogenetic and selection pressure analysis of core ANKdc-proteins from considered *Trichoderma* spp.

### 3 Materials and Methods

#### 3.1 Preliminary investigation

##### 3.1.1 Whole Genome and ANKdc-protein statistics among Hypocreales

JGI (Joint Genome Institute) Mycocosm website

(<https://genome.jgi.doe.gov/programs/fungi/index.jsf>) enables filtering of species at different taxonomical levels by using an interactive phylogram (Grigoriev *et al.* 2013). Genome statistics of all species from a selected subdivision, order or genus were downloaded and transferred into excel for data analysis. This data was used to create box plots of genome sizes and N° of gene models at different taxonomic levels from Ascomycota (division) to *Trichoderma* (species).

All species belonging to Hypocreales taxonomical level were filtered and by searching for “ankyrim” keyword in JGI search total number of ANKdc-proteins per species was obtained. All hits were transferred into excel and counted to obtain the number of ANKdc-proteins per species.

##### 3.1.2 Retrieval of putative ANKdc-protein sequences

All ANKdc-proteins from *Trichoderma guizhouense* NJAU 4742 (Druzhinina *et al.* 2018), *T. parareesei* TUCIM 717 (Yang *et al.* 2015) and *T. afroharzianum* LTR were obtained from a non-public local database based on already available annotations by InterProScan (Jones *et al.* 2014). The ANKdc-proteins from other 15 Hypocreales species were downloaded from JGI’s Mycocosm website. The keyword “ankyrim” was used in JGI website’s search function to find all proteins that contained at least one ANK-domain, based on JGI’s annotation. The ANKdc-protein sequences were downloaded in amino acid fasta format from genomes listed in Table 1.

Hypocrealean ANKyrome is the inventory of all ANKdc-proteins from 10 *Trichoderma* spp. and eight closely related non-*Trichoderma* Hypocrealean Genomes (NTHGs).

Note: This study is based on the assumption that protein domain assignments of the genomes carried out by JGI using their custom annotation pipelines are correct.

## 3.2 Re-annotations of Hypocrealean ANKyrome

### ANK-repeat annotations

The re-annotation of domains present in Hypocrealean ANKyrome was performed in batch by using Blast2GO software (Conesa *et al.* 2005, 2) with inbuilt InterProScan tool (Jones *et al.* 2014).

Three main databases for ANK repeat domain annotation implemented in InterProScan were Pfam (Bateman *et al.* 2004), Prosite (Hofmann *et al.* 1999) and SMART (Letunic, Doerks, and Bork 2011). The assigned IPR signature in InterProScan for ANK-repeat is IPR002110. ANK-repeats were filtered and to avoid duplicates specific database signature IDs for ANK-repeat were used. SMART database hits were filtered first, and the corresponding annotated proteins removed from the list. Then, the remaining proteins were filtered by Prosite and Pfam annotations, respectively.

### Host-domain annotations

The annotations of various host-domains associated with ANK-domains within the Hypocrealean ANKyrome were obtained from 14 different databases. Therefore, duplicate annotations had to be removed after a consensus for each host-domain was determined. The

cured annotations were used to find those host-domains that were present in higher abundance in *Trichoderma* spp. or in NTHGs. Then, these domains were compared at species level for each of 18 considered Hypocreales genomes. Furthermore, the most common host-domains in orphan proteins were investigated and compared to host-domain annotations in orthogroup proteins in *Trichoderma* spp.

#### *Determination of positional preference of ANK-repeats in T. virens ANKyrome*

After reannotation the position of each ANK-domain in ANKyrome from *T. virens* was visually determined and classified into 3 groups, N-terminal, C-terminal or Mid-section. *T. virens* was selected because it had the largest number of ANKdc-proteins in its ANKyrome.

### 3.3 Orthology Analysis of Hypocrealean ANKyrome

OrthoFinder v1.1.8 (Emms and Kelly 2015) was used to identify orthologs within the Hypocrealean ANKyrome obtained in 3.1.2 and then to group them into independent orthogroups. A complete OrthoFinder analysis was performed consisting of BLAST all-vs-all and MCL clustering, as described in the following paragraph. A multiple sequence alignment (MSA) of each orthogroup was performed as part of the OrthoFinder algorithm by using MAFFT auto strategy that selects an alignment method based on data size (Katoh *et al.* 2002; Katoh and Standley 2013).

#### *Curing and filtering of putative orthogroups*

The inferred MSAs of putative orthogroups were visually inspected and realigned in AliView (Larsson 2014) with MUSCLE (Edgar 2004) to detect misaligned regions more precisely. Certain putative orthogroups were split into separate orthogroups and some were rejected as orthogroups. ANKdc-proteins that were not assigned to any orthogroup will be referred to as orphan proteins in this thesis.

To confirm their orphan status, orphan ANKdc-proteins were subjected to second OrthoFinder analysis. The resulting orthogroups had to be filtered and cured as previously explained. Based on visual inspection of each orthogroup's alignment using Geneious (Kearse *et al.* 2012), a 23 % pairwise identity was accepted as threshold for orthogroups.

### OrthoFinder algorithm

An overview of steps in OrthoFinder algorithm is described in Figure 5. The first step of the algorithm is a BLAST all-versus-all (Altschul *et al.* 1990) with a higher than recommended E-value threshold of  $10^{-3}$  to prevent exclusion of very short sequences (Figure 5b).

In the second step BLAST bit scores are normalized to ensure that the best hit is assigned score independent of protein length or phylogenetic distance Bit scores are used because the lowest E-value is  $e^{-180}$  and no resolution of sequences with high similarities is achieved (Figure 5c).

In the next step, RBNHs (Reciprocal Best Length-Normalized hit) is calculated for each protein to set the lower limit for acceptance of putative orthologs (Figure 5d).

In the last two steps, putative orthologs are connected in the orthogroup graph based on normalized BLAST bit scores and then clustered into orthogroups using MCL (Figure 5f).

Figure 5: Overview of the steps in the OrthoFinder algorithm. Emms and Kelly 2015

### 3.3.1 UpSet analysis to reveal shared ANKYrome and core orthologous genes

Universal ANKdc-proteins shared by species of different taxonomical sections were determined by analyzing inferred orthogroups. The results were summarized and visualized using an R-package (Team 2013) UpSet (Lex *et al.* 2014). This tool visualizes set intersections quantitatively in a matrix layout. A set is defined as a collection of distinct elements that describes a common characteristic. ANKdc-proteins (distinct elements) inventory, or ANKYrome, from one species (common characteristic) was considered a single set. If at least one ortholog from each of two different species is present in same orthogroup, this orthogroup is considered an intersection between ANKYromes of these two species. By counting all orthogroups where at least one representative from each of these two species is present, the number of intersections between them is obtained. Accordingly, core *Trichoderma* orthogroups were considered to be those orthogroups that contained at least one representative of each of the 10 considered *Trichoderma* spp.

## 3.4 Evolutionary Analysis for core orthologous genes

### 3.4.1 Phylogenetic Analysis

#### *BLAST with representatives from core orthogroups*

Only four sequences, one from each taxonomical section of *Trichoderma* genus, *T. harzianum*, *T. virens*, *T. atroviride* and *T. reesei*, from each core orthogroup were used for similarity search by Geneious 10.2.2. batch BLAST (Kearse *et al.* 2012). A batch BLAST was performed by using an E-value cutoff of  $e^{-30}$ . The BLAST results were merged with the original orthogroups before curing. After preliminary alignment using Muscle, duplicates were removed, and only unique sequences were retained. Furthermore, accession numbers without species names were searched in NCBI Protein (Coordinators 2016) to find their corresponding source. Each orthogroup was visually inspected and realigned with MUSCLE. Non-homologs were removed in multiple iterative steps.

#### *Multiple sequence alignments*

The sequences were realigned using MAFFT accurate algorithm. Next, Gapstreeze tool (<https://www.hiv.lanl.gov/content/sequence/GAPSTREEZE/gap.html>) was used to remove flanking regions by assigning a threshold of 84-90% for gaps in aligned columns. Cured MSAs were used in following phylogenetic analysis.

### *Maximum Likelihood phylogeny inference*

Cured protein alignments were subjected to maximum likelihood phylogenetic estimation by uploading them to PhyML 3.0 public server (<http://www.atgc-montpellier.fr/phyml/>) (Stephane Guindon *et al.* 2005; Stéphane Guindon *et al.* 2010). An automatic substitution model selection was performed by SMS (Lefort, Longueville, and Gascuel 2017) by using the Bayesian Information Criterion. For the branch support of maximum likelihood phylogeny, 1000 bootstrap replicates were performed.

### *Bayesian phylogeny inference*

Two simultaneous, independent analyses starting from different random trees were run in MrBayes (Ronquist *et al.* 2012), each using three heated chains and one "cold" chain. Once the analyses were completed, 7500 trees were summarized after discarding the first 25% of the obtained 10,000 trees, resulting in a consensus tree.

The output was assessed based on a convergence diagnostic PSRF (Potential scale reduction factor) which compares variance within and between runs and had to be close to 1.0, otherwise the analysis had to be ran longer. If PSRF value was close to 1.0 the trees were summarized by removing 25 % of samples. The output contained a phylogram with mean branch lengths. The same substitution models selected for each alignment by SMS previously were also used in the Bayesian analyses.

## 3.4.2 Selection Pressure Analysis

### *Preparation of codon alignments with Pal2Nal*

Corresponding cDNA sequences for core protein ANKyrome were retrieved from JGI. PAL2NAL (Suyama, Torrents, and Bork 2006) online tool (<http://www.bork.embl.de/pal2nal/>) uses a protein MSA and its corresponding cDNA sequences to prepare a cDNA-MSA. Since cDNA sequences of proteins from *T. guizhouense* NJAU 4742, *T. parareesei* TUCIM 717 and *T. afroharzianum* LTR were not available, these genomes were excluded from subsequent analyses.

### *Preparation of Bayesian trees for Selection Pressure analyses*

The protein MSA alignments with reduced MOTUs that correspond to MOTUs in cDNA MSA were subjected to Bayesian phylogenetic analyses according to the procedure described in 3.4.1. Inferred trees were combined with codon alignments to obtain a nexus file necessary for selection pressure analyses.

### *Selection Pressure Analysis*

It has been shown that recombinant sequences lead to the false positive detection of positive selection in selection pressure analyses (Shriner *et al.* 2003). This can be prevented if the MSA is split into respective non-recombinant parts. For this purpose, Genetic Algorithm for Recombination Detection (GARD) for identification of non-recombinant fragments in an MSA was developed by Kosakovsky Pond *et al.* 2006. The nexus files containing both MSAs and trees were subjected to GARD. If a recombination breakpoint is detected in an MSA, the MSA is split into non-recombinant parts, which can be independently subjected to selection pressure analyses.

The first selection pressure analysis was performed by using BUSTED (Branch-Site Unrestricted Statistical Test for Episodic Diversification), a protein-wide positive selection pressure analysis. This tool indicates if at least one site or one branch in the protein has evolved under positive selection. The significant result is not conclusive, so further analyses at site-level are necessary for a complete hypothesis testing (Murrell *et al.* 2015).

In the next step, MEME (Mixed Effects Model of Evolution) tool was used. MEME is an algorithm for detection of episodic (on a subset of branches) positive selection pressure analysis at individual sites that allows the levels of positive selection to vary from branch to branch (Murrell *et al.* 2012). For the visualization of results  $\beta - \alpha$  ( $\beta$  is the relative rate of nonsynonymous substitutions,  $\alpha$  is the relative rate of synonymous substitutions) is used as a measure of the intensity of selection, because for small  $\alpha$  values the ratio  $\beta/\alpha = \omega$  is misleading ( $\omega = 1$  represents neutral evolution,  $\omega < 1$  negative selection and  $\omega > 1$  positive selection). Both MEME and BUSTED were used as online implementations on datamonkey.org server (Delpont *et al.* 2010).

In the last step of selection pressure analysis, FUBAR (Fast, Unconstrained Bayesian AppRoximation) tool was used. This tool is used for detection of pervasive (across whole

phylogeny) positive or purifying selection at individual sites based on a Bayesian approach (Murrell *et al.* 2013). The selection pressure for each site is constant along the whole phylogeny and the inferred rates are supported by their corresponding posterior probabilities. FUBAR was used as part of the offline HyPhy tool package (Pond and Muse 2005).

Inferences of selection pressure analysis were made based on results from all of the above-mentioned tools.

### 3.5 TMHMM and SignalP analyses

The Hypocrealean ANKYrome was subjected to signal peptide cleavage site prediction on the online server <http://www.cbs.dtu.dk/services/SignalP/> (Petersen *et al.* 2011). Furthermore, these proteins were also subjected to the prediction of transmembrane helices in proteins on the public server <http://www.cbs.dtu.dk/services/TMHMM/> (Sonnhammer, Von Heijne, and Krogh 1998). These analyses were used to detect trends in the share distribution of signal peptides and transmembrane helices in Hypocrealean ANKYrome and compare them on the species level.

### 3.6 Transcriptomic data analysis

Each protein from *Trichoderma* ANKYrome was screened against differentially expressed genes (RNA deepseq) obtained during dual confrontation assays of *Trichoderma guizhouense* NJAU 4742 and *Trichoderma harzianum* TUCIM 916 (=CBS 226.95) against *Fusarium oxysporum* f. sp. *cubense* 4 strain (Foc4). Transcriptional response was investigated in a confrontation of *T. guizhouense* against itself, against *T. harzianum* and finally against Foc4. The same approach was employed for *T. harzianum* (Zhang, Miao, Rahimi, Shen, Druzhinina, unpublished).

## 4 Results and discussions

### 4.1 Inventory of the *Trichoderma* ANKYrome

#### 4.1.1 Genome and ANKdc-protein statistics comparison

Genomes from the taxonomical order Hypocreales, including those that were considered in this study, that were selected for statistical comparison are presented in Table 2. The listed *Trichoderma* spp. belong to four different taxonomical sections also shown in the phylogram from Figure 2, the *Longibrachiatum*, *Harzianum*, *Trichoderma* and *Virens*, respectively. Within the *Trichoderma* genus, average genome size is 36.3 Mbp, while the average number of gene models is 11618. *T. harzianum* CBS 226.95 is the largest genome with highest number of gene models among all *Trichoderma* spp., whereas *T. parareesei* TUCIM 717 is the smallest genome. The *Longibrachiatum* section's genomes are generally smaller, when compared to the rest of considered *Trichoderma* spp. and this is also the youngest section among *Trichoderma* spp.

Genome	Genome size [Mbp]	N° of gene models	TAXONOMICAL SECTIONS
<i>Trichoderma reesei</i> Qm6a	34.1	9129	<b>LONGIBRACHIATUM</b>

Table 2: Hypocreales genomes that were used for characteristics comparison

### Comparison of Genome sizes between Hypocrealean and Non Hypocrealean spp

Data from JGI was used to compare all available species from Ascomycota level to Hypocreales level. At both Ascomycota and Pezizomycotina levels the largest genome is almost 180 Mbp, specifically the *Cenococcum geophilum* 1.58 from Dothideomycetes group. The second largest genome among all Ascomycota is *Blumeria graminis* f. sp. *tritici* 96224. The results are visualized in a box plot in Figure 6a.

In the second box plot in Figure 6b number of gene models (or JGI predicted gene) per species is compared. The largest number of genes are found in *Fusarium oxysporum* f. sp. *lycopersici* strain 4287.

Figure 6a and 6b: Box plots showing range of genome sizes and number of total proteins at different taxonomical levels

### *ANKdc-protein expansion in species of higher taxonomical orders*

The results of ANKdc-proteins abundance comparison in Hypocreales genomes are summarized in Table 3. In *T. virens* ANKdc-proteins account for 1.56 % of all gene models which is only superseded by *Ilyonectria robusta* PMI 751 inside the Hypocreales order. Some of the highest shares of ANKdc-proteins among considered Hypocreales species are found in *T. atroviride* with 1.3 %, *T. harzianum* with 1.27 %, *T. gamsii* with 1.22 % and *T. guizhouense* with 1.22 % of all genes. Below 1 % share of ANKdc-proteins are found in *Trichoderma* spp. from *Longibrachiatum* section. These findings are in concordance with results from the Druzhinina *et al.* unpublished work and confirm that the expansion of ANKdc-proteins in most aggressive *Trichoderma* spp. is present. But, according to these updated results the expansion is not exclusive to *Trichoderma* spp. even if only the species from Hypocreales order are taken into account. Two *Ilyonectria* spp. had the highest share of ANKdc-genes and also the highest total number of ANKdc-proteins. These genomes were sequenced and published in 2016 and 2017 so the data was not available at the time of preliminary investigation by Kubicek *et al.* in 2011. The species from *Ilyonectria* genus are common soil fungi that cause root rot as opportunistic phytopathogen but can also be found as endophytes of healthy plants (dos Santos *et al.* 2014).

#### 4.1.2 Retrieval of putative ANKdc-proteins from selected Hypocreales

Total number of mined ANKdc-proteins from the respective source species, along with minimum and maximum protein lengths are summarized in Table 4. The highest number of ANKdc-proteins are found in *Fusarium oxysporum*, which also has the largest number of proteins in general. Among *Trichoderma* spp. the most ANKdc-proteins were obtained from *T. virens*, while the least were present in *T. reesei*.

Organism Name	Genome Size [Mbp]	N° of Gene Models	N° of ANKdc-proteins	Share of ANKdc-proteins [%]

Table 4: Genome statistics in Hypocreales

#### 4.1.3 Re-annotated Hypocrealean ANKyrome

##### Annotation of ANK-repeats

From 2406 proteins from Hypocrealean ANKyrome 2036 had at least one annotated ANK repeat from at least one of the selected databases. All filtered hits were sorted by their database signature ID and the total number of hits per database are shown in Table 5.

	Database Signature ID	N° of annotations
Pfam	PF00023	373
	PF13606	105
Prosite	PS50088	6882
SMART	SM00248	13498
TOTAL	-	20858

Table 5: Annotations of ANK repeats per database

The results from Table 5 indicated that SMART database was superset of other two databases, which was additionally confirmed by randomly analyzing some proteins in online InterProScan and visual inspection of graphical outputs. For this reason, SMART annotations were filtered first, which resulted in annotation of 13502 ANK-repeats from 1961 out of 2406 query proteins. The annotations in remaining 445 proteins, were filtered first by Prosite and then by Pfam results. Finally, additional 75 ANK-repeats were obtained, for the total of 13581 annotated ANK-repeat sequences. The results are summarized in Table 6.

	Signature ID	N° of annotations
<b>SMART</b>	SM00248	13502
<b>Prosite</b>	PS50088	74
<b>Pfam</b>	PF00023	5
<b>TOTAL</b>		<b>13581</b>

Table 6: Source databases of final ANK-repeat annotations

N° of ANK-repeats per ANKdc-proteins on species level were analyzed and the results are shown in Figure 7 and the corresponding Supplementary material 1. On average there are 6.5 ANK-repeats per ANKdc-protein within the *Trichoderma* ANKYrome and within the NTHGs ANKYrome there are 6.9 ANK-repeats per ANKdc-protein on average. The most ANK-repeats per ANKdc-protein within the Hypocrealean ANKYrome were present in *T. guizhouense* with 9.4 followed by 8.5 ANK-repeats per ANKdc-protein in *T. afroharzianum*.

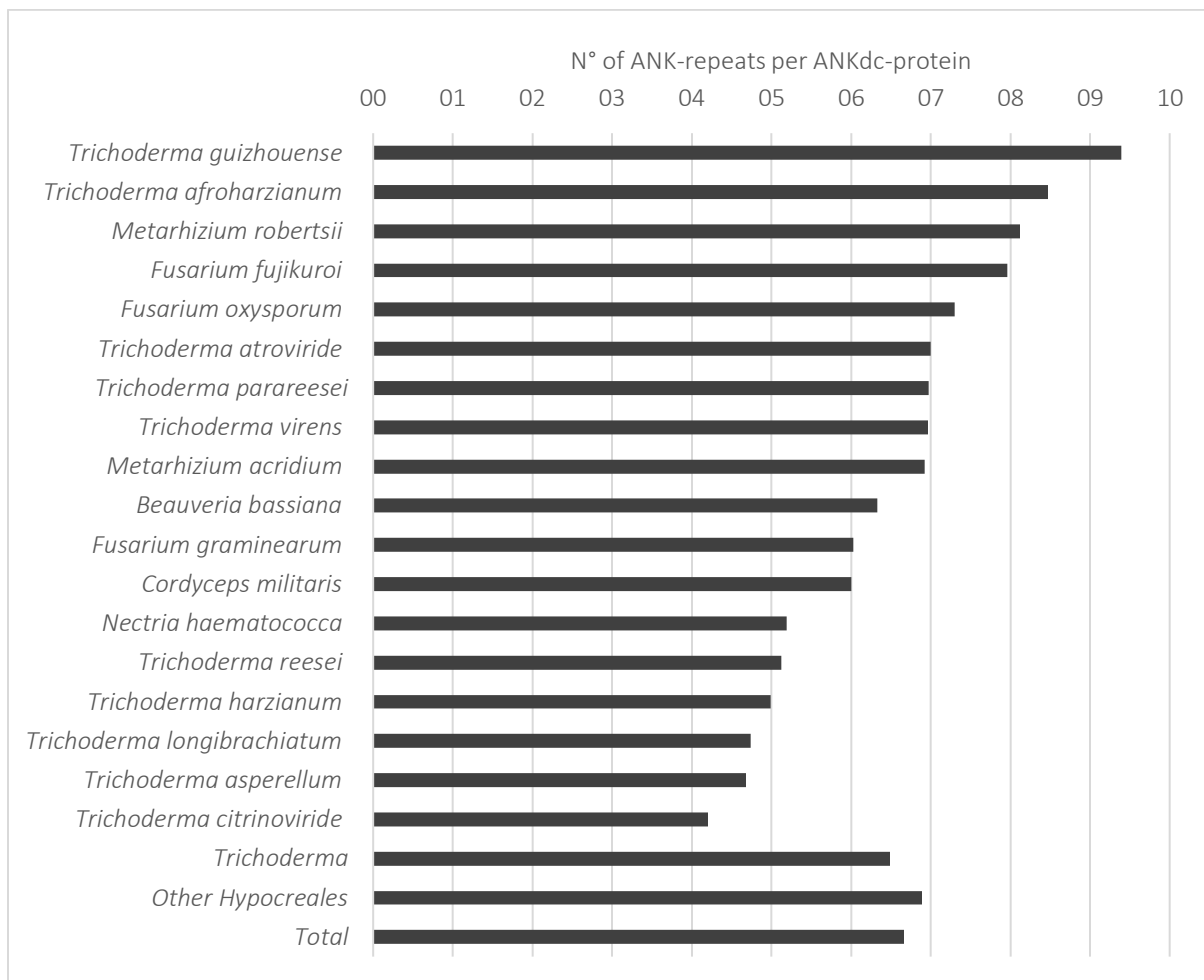

Figure 7: Comparison of number of annotated repeats per species

#### Host-domain annotation in ANKdc-proteins

According to InterProScan analysis results, 48.7% of ANKdc-proteins in the Hypocrealean ANKyrone contained ANK-domain as the only identified domain (loner-ANKdc-proteins). The ANKdc-proteins that contain other associated domains will be referred to as host-domain containing ANKdc-proteins (hdc-ANKdc-proteins) in this thesis.

In the *Trichoderma* ANKyrone of 1309 ANKdc-proteins, 49% or 642 proteins are hdc-ANKdc-proteins. The *T. guizhouense* and *T. afroharzianum* ANKyrone contained the highest share of hdc-ANKdc-proteins with 63% and 59%, respectively. *T. virens* ANKyrone has the lowest share of hdc-ANKdc-proteins with 37.1%, implying that most of the ANKdc proteins in *T. virens* are loner-ANKdc proteins. The complete list of hdc-ANKdc-proteins in individual species are shown in Figure 8 and Supplementary material 2

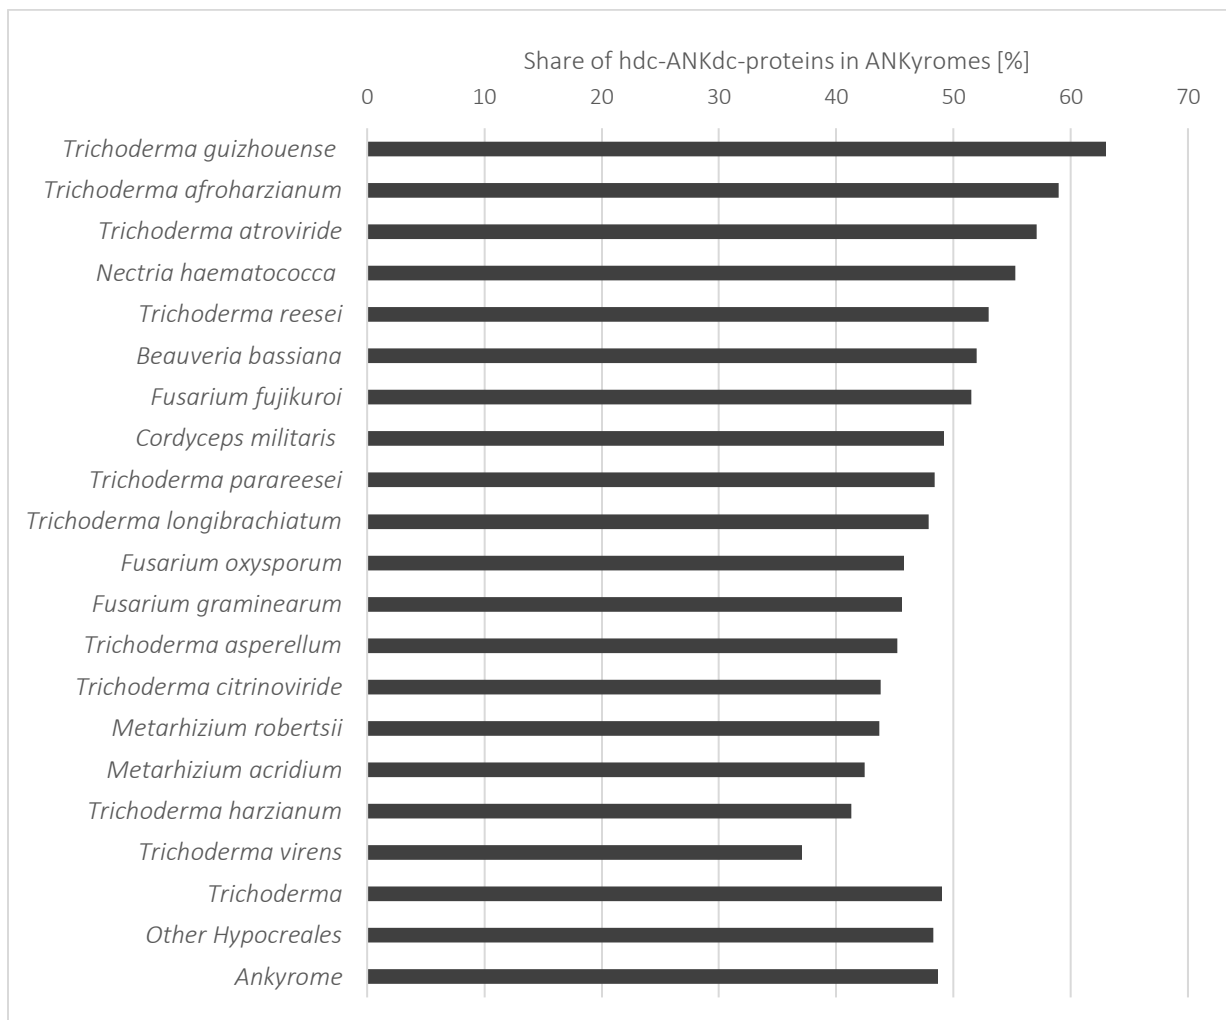

Figure 8: Share distribution of *hdc-ANKdc*-proteins in *Trichoderma* spp. and NTHGs

The share distribution of twelve most common associated domains found in *hdc-ANKdc*-proteins from *Trichoderma* spp. is shown in Figure 9, while the full list of annotations is given in Supplementary material 3.

The three most common domains that are associated with ANK-domain in *hdc-ANKdc*-proteins from *Trichoderma* ANKYrome are P-loop containing nucleoside triphosphate hydrolase (PLNTH), nucleoside phosphorylase (NP) and NACHT domain (named after proteins it is present in, NAIP: NLP family apoptosis inhibitor protein, CIITA: C2TA or MHC class II transcription activator, HET-E: incompatibility locus protein from *Podospora anserina* and TEP1: TP1 or telomerase-associated protein). PLNTHs are present in 24.5 % of *hdc-ANKdc*-proteins from *Trichoderma* spp. and in 26 % of *hdc-ANKdc*-proteins from NTHGs. The PLNTHs catalyze the hydrolysis of NTPs (specific for ATP/GTP) beta-gamma bond and the released energy is used for conformational changes in other molecules (Leipe, Koonin, and Aravind 2004).

NPs were found in almost 13 % of hdc-ANKdc-proteins from *Trichoderma* spp. and 19 % of hdc-ANKdc-proteins from NTHGs. Function of this domain depends on which kind of phosphorylase it encodes, eg PurineNP, UridineNP etc. It catalyzes the phosphorolytic breakdown of the N-glycosidic bond to the respective nucleoside and sugar-1-phosphate molecules, which are either used as carbon and energy sources or for nucleotide synthesis (Takehara *et al.* 1995).

The next most common host-domain in *Trichoderma* ANKYrome is NACHT. This domain consists of ATP/GTPase specific P-loop domain, the Mg<sup>2+</sup>-binding site (Walker A and B motifs, respectively) and five more specific motifs. It is essentially a modified nucleoside phosphatase, but its function remains unknown (Koonin and Aravind 2000).

Further most common domain in *Trichoderma* ANKYrome is protein kinase (PK), F-box and heterokaryon incompatibility motifs (HET). Each of these domains was present in around 5 % of hdc-ANKdc-proteins from *Trichoderma* spp.

PKs catalyze the transfer of gamma phosphate groups from NTPs on proteins. Their function in cells is associated with division, proliferation, apoptosis, and differentiation (Hanks, Quinn, and Hunter 1988).

F-box domain is a part of the E3 ubiquitin ligase complex which beside F-box, contains Skp and Cullin domains. This complex catalyzes the ubiquitination of proteins for their degradation by proteases. The function of F-box is to connect the target protein with Skp (OmpH Chaperone protein) and thereby bring it closer to the E2 enzyme that is loaded with ubiquitin (Kipreos and Pagano 2000).

Filamentous fungi use individual specific HET domains as self-/non-self-discrimination during vegetative fusion. Heterokaryotic cells produced by vegetative fusion of genetically different cells trigger the vegetative incompatibility associated programmed cell death reaction (Paoletti and Clave 2007).

Figure 9: Share distribution of the most common host-domains found in hdc-ANKdc-proteins from *Trichoderma* spp.

The distribution of host-domains was compared between orphan and orthogroup ANKdc-proteins from *Trichoderma* ANKYrome and the results are shown in Figure 10. The two most common host-domains in *Trichoderma* ANKYrome, NP and PLNTH, are predominantly found in orphan ANKdc-proteins. The annotations were sorted based on the largest absolute differences between orphan and orthogroup ANKdc-proteins. There are 123 ANKdc-proteins containing NP domain of which 82% are orphan proteins. Almost 70% of ANKdc proteins containing PLNTH domain are orphan proteins. Furthermore, 85 % of Peptidase S8/S53 domain annotations were found in orphan proteins of hdc-ANKdc proteins from *Trichoderma* spp.

NWD-NACHT NTPase, Sigma domain on NACHT NTPase, BTB/POZ, Kila, HTH, PK, SPX, F-box, Allantoicase, Phosphodiesterase domain were predominantly found in ANKdc-proteins that belong to orthogroups.

In general, 41 % of all 642 *Trichoderma* hdc-ANKdc-proteins are orphan.

Figure 10: Host-domain annotation distribution comparison between *Trichoderma orphan* ANKdc-proteins and orthogroup ANKdc-proteins

A direct comparison of share distributions of annotated domains in ANKdc-proteins between *Trichoderma* spp. and NTHGs. was performed to identify group specific host-domains. 20 annotated domains with largest difference in their share abundance among hdc-ANKdc-proteins between *Trichoderma* spp. and NTHGs are shown in Figure 11.

Largest difference was found in NP domain abundance, which was present in 19 % of hdc-ANKdc-proteins from *Trichoderma* spp. and 13 % of hdc-ANKdc-proteins from NTHGs. The most significant difference is the absence of Eisosome protein SEG1/Sle1 in ANKyromes from NTHGs, which was found in almost 4 % of hdc-ANKdc-proteins from *Trichoderma* spp. The function of this protein is unknown.

Other important differences are increased share of ANKdc-proteins containing PK and F-box domains in Hypocreales, but also an increased share of NWD-NACHT NTPase, Sigma domain on NACHT NTPase, NACHT and WD40 repeat domain containing ANKdc-proteins in *Trichoderma* ANKyrome.

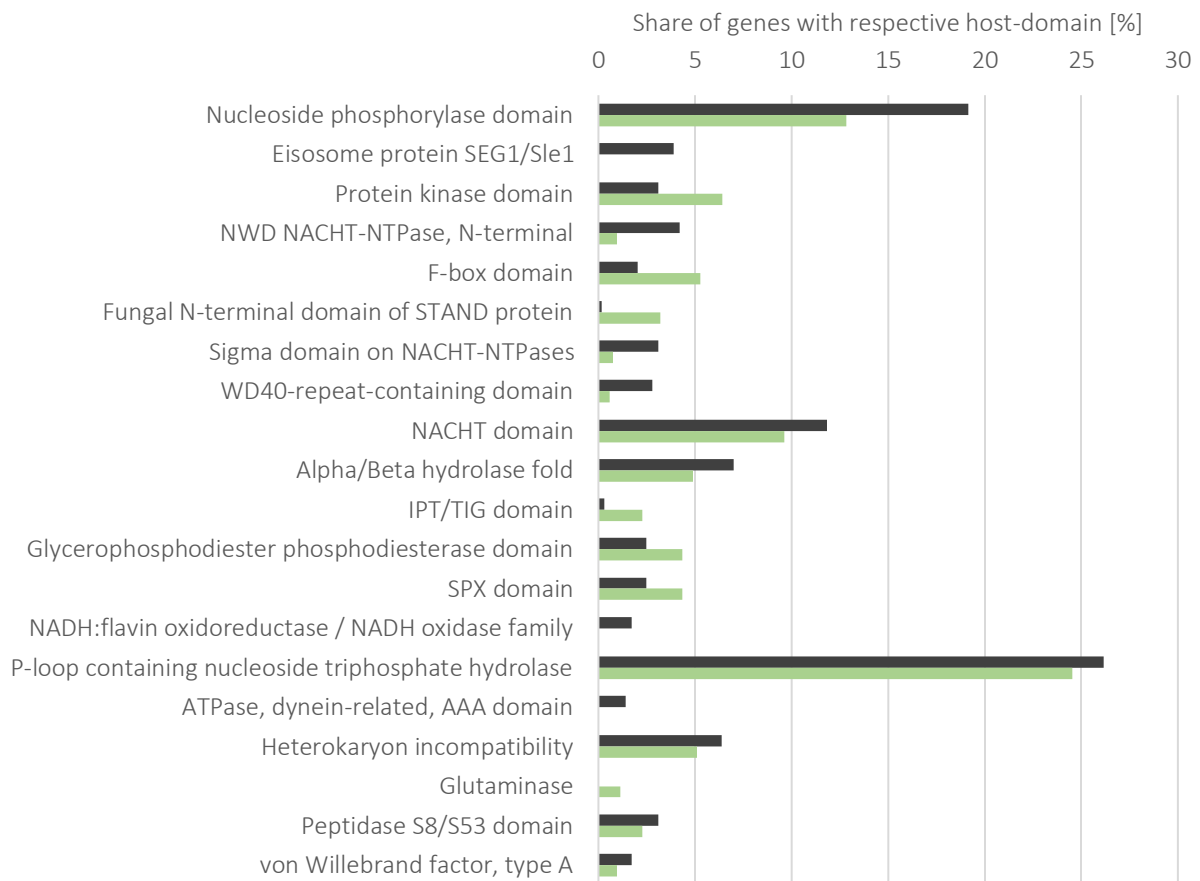

Figure 11: Host-domains annotations with largest differences in their share abundance among hdc-ANKdc-proteins between *Trichoderma spp.* and NTHGs

#### Comparison of host-domains at the species level

To get a deeper insight into the distribution of host-domains with largest differences in abundance between ANKdc-proteins from *Trichoderma spp.* and ANKdc-proteins from NTHGs, they were investigated at the level of individual species. The results are presented in Figure 12 and Figure 13 and corresponding Supplementary material 3.

**Nucleoside phosphorylase** domain containing ANKdc-proteins made up the largest share of hdc-ANKdc-proteins with 27 % or 24 of all hdc-ANKdc-proteins from *T. guizhouense*, while in *T. virens* and *T. harzianum* it was found in 25 % and 24 % of all hdc-ANKdc-proteins, respectively (18 proteins each). This type of ANKdc-proteins made up the lowest share of all hdc-ANKdc-proteins in *C. militaris*, accounting only for 3.3 % of all hdc-ANKdc-proteins.

**Eisosome protein SEG1/Sle1** is a host-domain specific for ANKdc-proteins from *Trichoderma spp.* as it was not present in hdc-ANKdc-proteins from NTHGs. It is found in 8 % (6 ANKdc-proteins) of *T. harzianum* and 7 % (5 ANKdc-proteins) of hdc-ANKdc-proteins from *T. virens*. But, it is not present in any of hdc-ANKdc-proteins from *T. parareesei*.

Protein kinase domain made up 12 % (15 proteins) of hdc-ANKdc-proteins from *F. oxysporum*, which was by far the largest share % of all analyzed species and the largest absolute number of proteins.

NWD NACHT-NTPase, N-terminal domain is found in 6.9 % in *T. virens* and 6.5 % in *T. asperellum*. It is mostly found in *Harzianum* and *Trichoderma* sections with five to four proteins, while other species either have only one or no proteins containing this domain.

**F-box domain** is present in 9% of of hdc-ANKdc-proteins from *B. bassiana* and 8 % from *F. oxysporum*. It is important to mention, that the absolute number is highest in *F. oxysporum* with 10 proteins in total, while *B. bassiana* has five ANKdc-proteins containing this domain. Each considered *Trichoderma* sp. has one F-box domain containing ANKdc-protein except for species from *Trichoderma* section and *T. longibrachiatum* which have two ANKdc-proteins of this kind.

**Fungal N-terminal domain of STAND protein** was almost exclusively found in Phytopathogens except for *T. parareesei* which had only one ANKdc-protein with this host-domain. *F. oxysporum* had the most with eight (6.6 %) and *F. fujikuroi* with five proteins (6 %) with this host-domain. The function of this domain is unknown.

**Sigma domain on NACHT-NTPases** was present in three proteins in each of the species of *Harzianum* section. The most ANKdc-proteins were found in *T. virens* and *T. atroviride* as each have four ANKdc-proteins with this domain. With the exception of *T. longibrachiatum*, which had one ANKdc-protein containing this domain, this domain was almost absent from the *Longibrachiatum* section.

**WD40-repeat-containing domain** is most common in *Harzianum* section, where 6.1 % of all hdc-ANKdc-proteins in *T. afroharzianum*, 4.6 % in *T. guizhouense* and 4.1 % in *T. harzianum* contain this domain. In the *Longibrachiatum* section *T. reesei* and *T. parareesei* each have two ANKdc-proteins (4%) containing this domain.

In *Trichoderma* spp., **NACHT domain** is predominantly found in ANKdc-proteins of *Harzainum* section. In *T. guizhouense* 21.8 % of all hdc-ANKdc-proteins or 19 ANKdc-proteins in total contain this domain, while *T. afroharzianum* and *T. harzianum* have 10 and nine of these ANKdc-proteins, respectively. In Hypocreales, *F. oxysporum* has 12, *F. fujikuroi* 11 and *M. robertsii* nine NACHT domain containing ANKdc-proteins in total.

IPT/TIG domain is only present in ANKdc-proteins from *Trichoderma* section and NTHGs. Each species contains only one ANKdc-protein with this domain, whereas only *F. oxysporum* has five proteins of this kind.

**Glycerophosphodiester phosphodiesterase domain** and **SPX domain** are only absent in hdc-ANKdc-proteins from *T. reesei*, *T. citrinoviride* and *T. longibrachiatum*.

**NADH:flavin oxidoreductase / NADH oxidase domain family** is specific to hdc-ANKdc-proteins from *Trichoderma* spp. *T. parareesei* has two proteins with this host-domain, while other *Trichoderma* spp. have only 1 ANKdc-protein each.

Heterokaryon incompatibility domain was present in eight (13.5 %) hdc-ANKdc-proteins from *F. fujikuroi*, seven from *T. afroharzianum* and six from *T. guizhouense* and *T. parareesei* each.

**Glutaminase** was not present in any of hdc-ANKdc-proteins from *Trichoderma* spp. It is found in one ANKdc-protein in each of the Phytopathogens section species and in *B. bassiana* and *C. militaris*.

**Concanavalin A-like lectin/glucanase domain superfamily** and **SPRY domain** were predominantly found in hdc-ANKdc-proteins from *T. guizhouense*, where each host-domain was present in 8.5 % (5 ANKdc-proteins) of hdc-ANKdc-proteins.

**ATPase, dynein-related, AAA domain** was exclusively present in species of *Trichoderma* genus. Each species contained one hdc-ANKdc-protein of this type, but it was absent in *T. parareesei*.

**P-loop containing nucleoside triphosphate hydrolase (PLNTH)** containing ANKdc-proteins are present in highest numbers in *F. oxysporum* with 33 and *F. fujikuroi* with 29 ANKdc-proteins. The highest share of hdc-ANKdc-proteins of this type was found in *T. virens* with 36.1 % (26 ANKdc-proteins), *F. fujikuroi* with 34.5 % and *T. citrinoviride* with 33%, but it was also expanded in species of *Harzianum* section where each species had more than 20 hdc-ANKdc-protein with this domain. Furthermore, in *T. atroviride* there were 26 ANKdc-proteins containing this domain, while in *T. asperellum* only 12 ANKdc-proteins of this type were present.

**Leucine-rich repeat domain superfamily** and **GAR domain profile** containing ANKdc-proteins are specific to *Longibrachiatum* taxonomical section except for *T. parareesei*.

The majority of host-domains from Hypocrealean ANKYrome are involved in essential cellular functions. As an example, it can be assumed that NTPases are associated with ANK-domain because it can recognize and specifically direct the enzyme to the place where produced energy is needed. The same can be applied to other above-mentioned host-domains.

Figure 12: Share distribution of host-domains among hdc-ANKdc-proteins at the species level (1st part)

Figure 13: Share distribution of host-domains in hdc-ANKdc-proteins at the species level (2nd part)

### Annotation of core orthogroups

11 out of 18 *Trichoderma* spp. core orthogroups consisted of loner-ANKdc-protein. Proteins belonging to these orthogroups contained exclusively ANK-domains. The other 7 orthogroups, which consisted of hdc-ANKdc-proteins, were also core orthogroups for the Hypocrealean ANKYrome. The annotations of ANKdc-proteins from these orthogroups and descriptions of their putative functions are shown in Table 7.

Orthogroup	Associated Domains	Function
16	VPS9	Vacuolar protein sorting- (fungal) transport of proteins from biosynthetic and endocytic pathways into the vacuole
	Phox homologous	Cell signaling, vesicular trafficking, protein sorting, lipid modification and protein-protein interaction
17	Allantoicase	Allantoate amidinohydrolase- catalyzes a step in uricolytic pathway: allantoate + H <sub>2</sub> O = (S)-ureidoglycolate + urea
	Dilute	Associates myosins with different organelles, membrane vesicles mRNA; Myosins are molecular motors
20	Palmitoyltransferase, DHHC	Post-translational modification; transfers palmitoyl group from palmitoyl-CoA to the thiol group of Cys residues
26	BTB/POZ	Transcriptional regulators
28	PH-Pleckstrin	Recruiting proteins to different membranes
	Oxysterol-binding protein	signaling, vesicular trafficking, lipid metabolism, and non-vesicular sterol transport.
30	HTH, APSES-type DNA-binding	Transcription regulator, <i>N. crassa</i> : role in spore maturation. <i>A. nidulans</i> : transformation of undifferentiated hyphal elements into a complex multicellular structure <i>Candida albicans</i> (Yeast): enhanced filamentous growth protein
31	L-asparaginase N and C terminal	Catalyzes deamination of asparagine to aspartic acid

Table 7: Summarized InterProScan results for core hdc-ANKdc-proteins

#### 4.1.4 Orthology Inference within the Hypocrealean ANKYrome

OrthoFinder analysis with total 2406 ANK-dc proteins resulted in 200 putative orthogroups that had to be filtered by visual inspection based on homology between MOTUs. After this step, 140 orthogroups containing 1053 proteins, as well as 1353 proteins as putative orphans (these proteins were not assigned to any orthogroup) were obtained. To verify their orphan status, a new OrthoFinder analysis was performed with only putative orphans from the previous step.

After visual inspection, further 43 orthogroups, containing 119 proteins, were identified. The main reason why further orthogroups were identified is the calculation of RBNHs (Reciprocal Best Length-Normalized hit) which led to less strict lower limit for acceptance of putative orthologs as explained in 3.3.

In conclusion, out of 2406 proteins 1172 were assigned to 183 separate orthogroups, while the remaining 1234 proteins were classified as orphan proteins.

A closer look into the number of orphan ANKdc-protein per species is shown in Figure 14 and the corresponding Supplementary material 4. The results reveal that the largest share of *Nectria haematococca* ANKYrome are orphans with 71% of all ANKdc-proteins. Within the *Trichoderma* genus, 61 % of *T. virens* ANKYrome are orphans, followed by *T. asperellum* ANKYrome which has 60.7 % orphans. In the ANKYromes from *T. parareesei* and *T. afroharzianum* orphans account for 33.7 % and 36.7 %, respectively.

Figure 14: Share of orphan ANKdc-proteins per species

#### 4.1.5 UpSet visualization of ANKyrome intersections

ANKdc-proteins shared between different taxonomical sections are shown in Figure 15. The connected dots represent which sections are being considered, while the corresponding column with the number on top corresponds to the total number of orthogroups in which respective species are present.

Out of 183 orthogroups only 18 orthogroups contained at least one representative from each of 10 considered *Trichoderma* species. This implies only 18 ANKdc-proteins are present in all of the 10 considered *Trichoderma* genomes. These 18 orthogroups represent the core ANKdc-proteins for *Trichoderma* spp.

Highest number of shared ANKdc-proteins were found in *Harzianum* section, to which *T. harzianum*, *T. afroharzianum* and *T. guizhouense* belong. Furthermore, only 11 core ANKdc-proteins among the 18 considered Hypocreales spp. were detected.

Figure 15: UpSet visualization of ANKyrome orthogroup intersections by taxonomical sections

**Phytopathogens** are plant pathogenic fungi *Nectria haematococca*, *Fusarium oxysporum*, *F. graminearum*, and *F. fujikuroi*.  
**Entomopathogens** are insect pathogenic fungi *Beauveria bassiana*, *Cordyceps militaris*, *Metarhizium acridum* and *M. robertsii*.

## 4.2 Evolutionary Analysis

### 4.2.1 Phylogenetic Analysis

The best substitution model determined by SMS for each MSA as well as the N° of taxa in each MSA are listed in Supplementary material 5.

The inferred phylogenetic trees will be interpreted individually but there are some general characteristics which should be mentioned before. The topologies of trees inferred by Maximum likelihood and Bayesian method were similar and congruent with the multilocus gene genealogy of Hypocreales from Figure 2. The taxonomical sections *Longibrachiatum*, *Harzianum*, *Virens* and *Trichoderma* were consistently identifiable in each tree topology. The node support values in Maximum likelihood trees are shown explicitly, where well supported nodes had bootstrap values greater than 50%. The Bayesian inferred trees were manually processed by adding a grey circle to nodes that had a posterior probability  $\geq 95\%$ . The nodes of *Trichoderma* spp. clades were predominantly well supported in both phylogenetic analyses. Only Bayesian trees are included since there was no significant difference in comparison to Maximum likelihood trees.

The trees were grouped for interpretation based on species they contained as shown in Table 8.

Class	Sordariomycetes														Leotiomycetes		Microbotryomycetes	
	Hypocreomycetidae				Sordariomycetidae				Xylariomycetidi		Erysiphales		Helotiales		Leucosporidiales		Microbotryales	
Subclass	Hypocreales	Microascales	Glomerellales	Sordariales	Conio	Diaporthales	Ophiostomatales	Magnaporthales	Togniniales	Xylariales	Erysiphales	Helotiales	Leucosporidiales	Microbotryales

Table 8: Summary of taxonomical range of MOTUs present in phylogenetic trees

### Phylogenetic trees 39, 48, 58

The MSAs 39, 48 contained exclusively *Trichoderma* spp. homologs including proteins from *T. gamsii*. The MSA 58, in addition to all *Trichoderma* spp. proteins, had only one homologous protein outside *Trichoderma* genus that originated from *Oidiodendron maius* (Ascomycota, Leotiomycetes). *Oidiodendron* spp. are symbionts of roots of Ericaceae plants so they belong to a group called Ericoid mycorrhizal fungi. These species improve nutrient exchange and protect the plant from heavy metal toxicity. A comparative genomics study from 2018 found that Ericoid mycorrhizal fungi are more similar to saprotrophs and pathogens than to ectomycorrhizal fungi based on their genetic machinery and secondary metabolism but also that they can be both saprotrophs and biotrophs (Wei *et al.* 2016; Martino *et al.* 2018). The corresponding trees are shown in Figure 16, Figure 17 and Figure 18.

Figure 16: Bayesian tree of OG 39

Figure 17: Bayesian tree of OG 48

Figure 18: Bayesian tree of OG 58

## Phylogenetic trees 22, 23, 31, 50

All of these trees contained exclusively homologs from species belonging to the Hypocreales order. The corresponding trees are shown in Figure 19, Figure 20, Figure 21 and Figure 22.

Figure 19: Bayesian tree of OG 22

Figure 20: Bayesian tree of OG 23

Figure 21: Bayesian tree of OG 31

Figure 22: Bayesian tree of OG 50

### Phylogenetic tree 64

The MSA 64 and its corresponding tree contained only proteins from *Trichoderma* spp. but no *T. gamsii* protein. The homologs from *T. gamsii* were found by homology search and were not included in the initial orthology inference because the genome was not available. The orthology inference can be repeated after retrieval of ANKyrome from published *T. gamsii* genome to eventually reject this orthogroup. The corresponding tree is shown in Figure 23.

Figure 23: Bayesian tree of OG 64

Phylogenetic trees 25, 66

The MSA 66 contained in addition to species from Hypocreales order homologs from Glomerellales order, while the phylogenetic tree 25 contained also species from Microascales order. The corresponding trees are shown in Figure 24 and Figure 25.

Figure 24: Bayesian tree of OG 25

Figure 25: Bayesian tree of OG 66

Phylogenetic trees 20, 26 and 30

In these phylogenetic trees species from both Hypocreomycetidae and Sordariomycetidae subclasses are found. Also, in each of the trees there are species from Xylariales order. The corresponding trees are shown in Figure 26, Figure 27 and Figure 28.

Figure 26: Bayesian tree of OG 20

Figure 27: Bayesian tree of OG 26

Figure 28: Bayesian tree of OG 30

Phylogenetic trees 16, 17

Here all MOTUs are from Sordaryomycetes class but in contrast to the phylogenetic trees 20,26 and 30 species from certain orders are missing. In both phylogenetic trees 16 and 17 homologs from species of Diaporthales order are missing. Furthermore, in the MSA 16 there are no representatives of Microascales, Sordariales and Togniales orders and only one species from Xylariales order is present. In the MSA 17 species from Ophiostomatales and Xylariales orders are not present. The corresponding trees are shown in Figure 29 and Figure 30.

Figure 29: Bayesian tree of OG 16

Figure 30: Bayesian tree of OG 17

Phylogenetic trees 21, 28

In the phylogenetic tree 21 species from all of the above-mentioned orders from Hypocreales to Xylariales but also two additional homologs from Erysiphales and Helotiales orders (Leotiomycetes) have been found. In the MSA 28 the same orders are represented with the exception of Sordariales and Coniochaetales orders. The corresponding trees are shown in Figure 31 and Figure 32.

Figure 31: Bayesian tree of OG 21

Figure 32: Bayesian tree of OG 28

Phylogenetic tree 43

The phylogenetic tree 43 contains homologs from all above-mentioned orders of Hypocreomycetidae subclass of all orders from Sordariomycetidae subclass only Diaporthales order is represented. Furthermore, homologs from Xylariales and Helotiales orders were found as well as homologs from species belonging to Leucosporidiales and Microbotryales orders from Basidiomycota.

Surprisingly, none of the phylogenetic trees contained MOTUs from Eurotiomycetes and Dothideomycetes classes. The corresponding tree is shown in Figure 33.

Figure 33: Bayesian tree of OG 43

#### 4.2.2 Selection Pressure Analysis

At  $p = 0.01$  GARD found no evidence of recombination breakpoints in any of the 18 analyzed MSAs. Therefore, selection pressure analysis was performed without splitting of MSAs.

BUSTED was used by specifying forward branches in each MSA. In six out of 18 core ANKdc-proteins BUSTED found no evidence of positive diversifying selection in any of sites or along branches. It detected evidence of positive diversifying selection in a very low percentage  $< 1\%$  of sites in three proteins. In another six ANKdc-proteins it found evidence of positive diversifying selection in a low percentage of sites  $\geq 1\%$  and  $< 3\%$ . The remaining three proteins had more than  $15\%$  of sites that were under positive selection, whereas MSA 50 contained almost one third of sites that were under positive selection. Model selection for each MSA is shown in Supplementary material 6.

MEME also found no sites under positive selection in MSAs 20 21 and 23, which is in congruence with the findings from BUSTED. In the remaining MSAs where BUSTED found no evidence of positive selection, MEME found 2 sites under positive selection in MSAs 16 and 43, which translates into  $0.1\%$  and  $1.5\%$  of all sites, respectively, while it detected eight sites, or  $0.4\%$  of sites, under positive selection in MSA 22.

In most of the remaining MSAs a very low percentage ( $< 1\%$ ) of sites was identified under positive selection by MEME, which is mostly in concordance with results from BUSTED. The largest deviations were present in MSAs that according to BUSTED contained more than  $15\%$  of sites under positive selection. In the MSA 25 MEME found evidence of positive selection in  $0.6\%$  (5) of sites, in MSA 39 only  $0.9\%$  (5) of sites and in MSA 50 only  $1.1\%$  (eight sites) of all sites. Model selection for each MSA is shown in Supplementary material 6.

FUBAR found evidence of pervasive positive selection at  $\geq 0.95$  posterior probability only in 3 proteins. In most MSAs  $60\%$  to  $90\%$  of sites were under purifying (negative) selection based on the FUBAR analysis at  $\geq 0.95$  posterior probability. In MSA 66  $49\%$  of sites and in MSA 48  $41\%$  of sites were under negative selection pressure. Negative selection was detected in least number of sites in MSAs 58, 64, 39 and 50 ranging from  $33\%$  to  $6\%$  of sites.

Model selection for each MSA is shown in Supplementary material 6.

*The results from all analyses are summarized in*

Table 9.

	<b>BUSTED</b>	<b>FUBAR</b>		<b>MEME</b>	
<i>Threshold</i>	$p = 0,05$	<i>posterior probability 0.95</i>		$p = 0,05$	
Orthogroup	Evidence of diversifying selection	N° of sites diversifying selection	N° of sites purifying selection	N° of sites diversifying selection	N° of sites in MSA
16	no	0	1176	2	1398
17	yes	0	949	3	1274
20	no	0	600	0	757
21	no	0	204	0	272

Table 9: Summary of selection pressure analyses BUSTED, FUBAR, MEME

### 4.3 TMHMM and SignalP analysis

The largest share of ANKdc-proteins with at least one transmembrane helix (TMH) were found in *C. militaris*. Among *Trichoderma* spp., *T. virens*, *T. afroharzianum* and *T. guizhouense* had the largest share of ANKdc-proteins containing at least one TMH (Figure 34).

In conclusion, the share of proteins with transmembrane helices in Hypocrealean ANKYrome is on average very low, so the function of ANKdc-proteins in *Trichoderma* spp. is not exclusively associated with cell membranes.

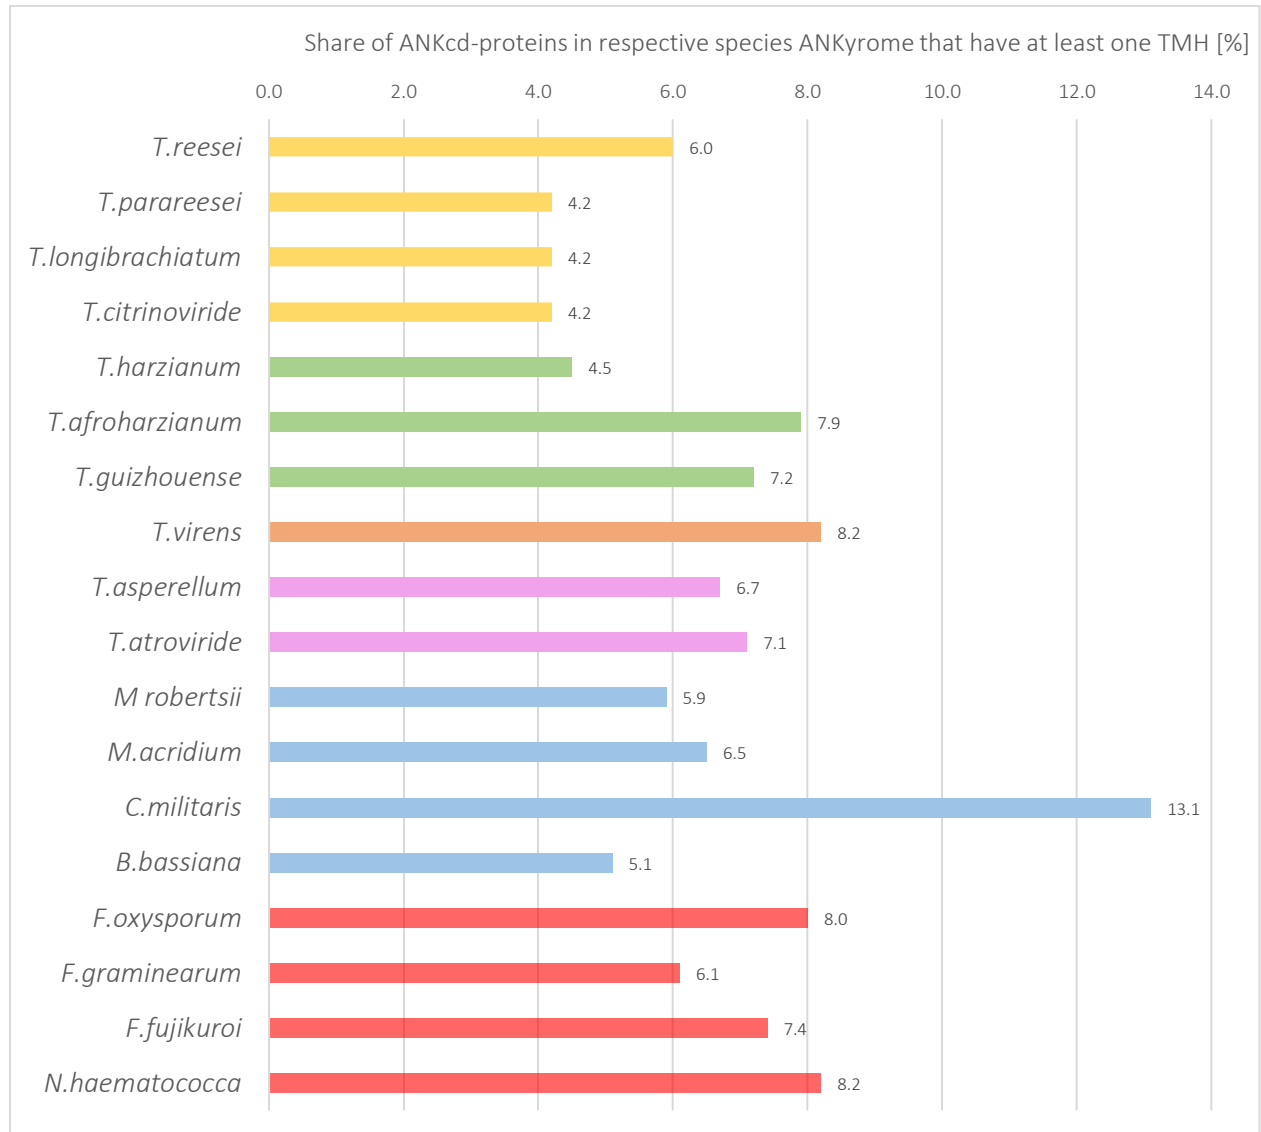

Figure 34: Normalized TMHMM results from Hypocrealean ANKYrome

The largest share of ANKdc-proteins with at least one signal peptide cleavage site were found in *T. reesei* followed by *T. virens*. If absolute numbers of signal peptide containing ANKdc-proteins is considered, the highest number was found in *T. virens* with 11 ANKdc-proteins containing signal peptide cleavage sites (Figure 35).

In conclusion, the share of ANKdc-proteins with signal peptides is on average is also very low, so the function of ANKdc-proteins is not limited to cell signaling pathways in *Trichoderma* spp.

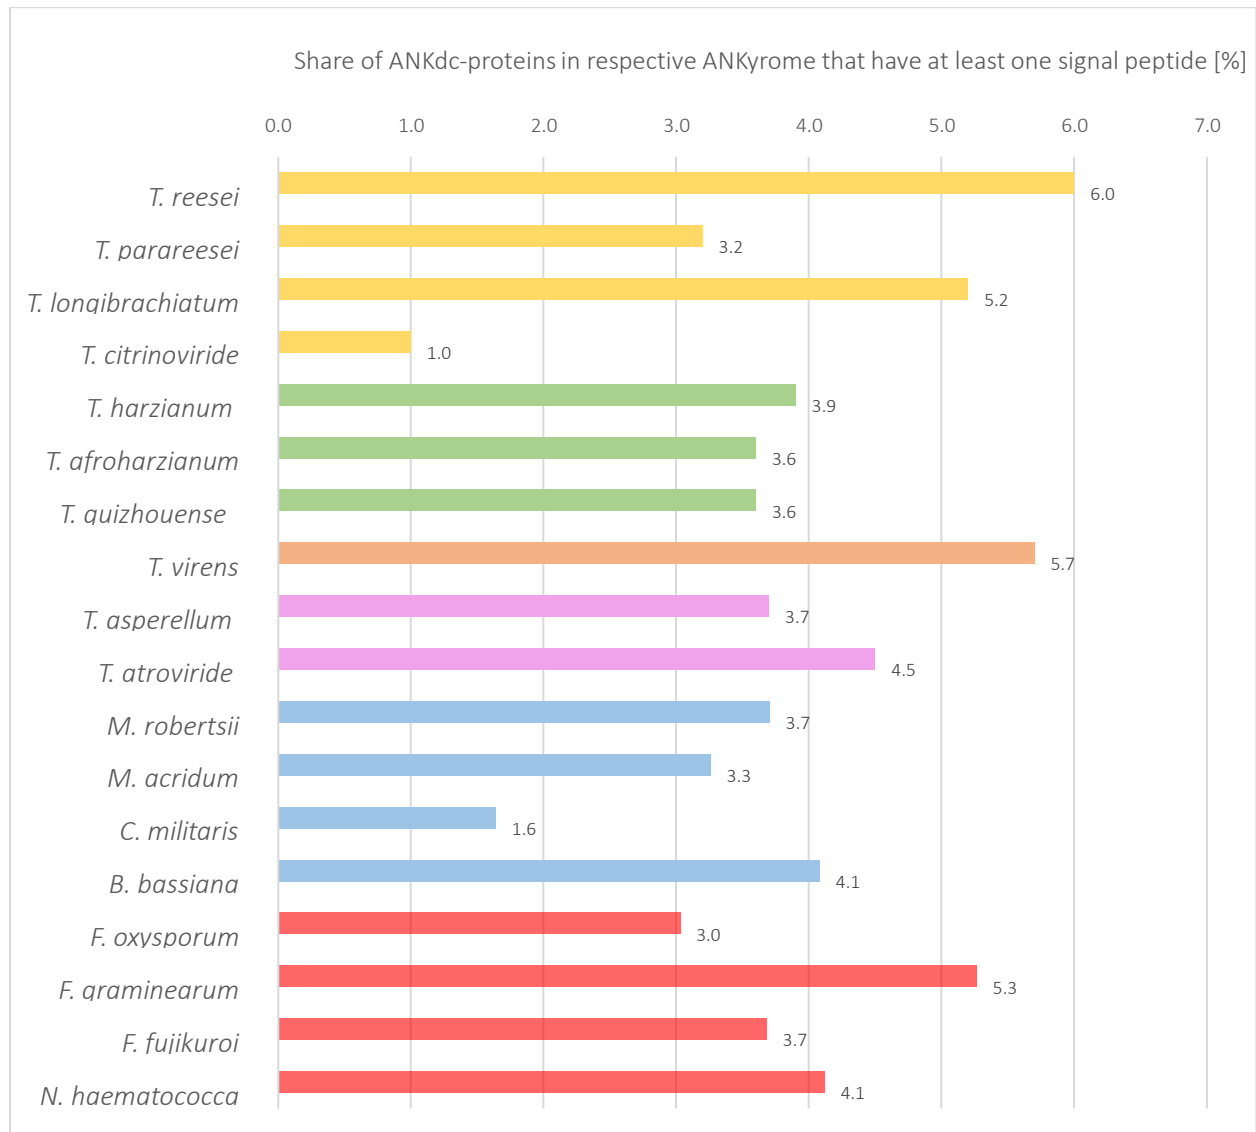

Figure 35: Normalized SignalP results from Hypocrealean ANKYrome

## 4.4 Transcriptomic data analysis

### 4.4.1 Differential Gene Expression results from *T. guizhouense* NJAU 4742

The search for ANKdc-proteins in DGE results from *T. guizhouense* transcriptomic analysis are summarized in Table 10. The search revealed a Nucleoside phosphorylase (NP) domain containing ANKdc-protein in *T. guizhouense* (NJAU 4742) which was significantly downregulated after contact with itself, with *T. harzianum* (TUCIM 916 = CBS 226.95) and with *F. oxysporum* (Foc4). Furthermore, two ANKdc-proteins; Protein-kinase (PK) domain containing ANKdc-protein, as well as a PLNTH and Alpha/beta hydrolase fold domain containing ANKdc-protein were significantly upregulated in each of the three confrontation assays.

The expression of seven ANKdc-proteins was upregulated in *T. guizhouense* both after contact with *T. harzianum* and after contact with *F. oxysporum*. Among these proteins, the most significantly upregulated protein is a von Willebrand factor, type A domain containing ANKdc-protein.

The expression of one loner-ANKdc-protein was significantly upregulated and one P-loop containing nucleoside triphosphate hydrolase (PLNTH) domain containing ANKdc-protein was significantly downregulated in *T. guizhouense* exclusively after contact with itself and with *T. harzianum*. The PLNTH containing ANKdc-protein was eight times more downregulated in *T. guizhouense* after contact with itself, compared to confrontation with *T. harzianum*.

Eight ANKdc-proteins were upregulated in *T. guizhouense* both after contact with itself and with *T. harzianum*. The most strongly upregulated expression was observed in a loner-ANKdc-protein OPB40539.

The expression of six ANKdc-proteins was downregulated in *T. guizhouense*, while the expression of one Sigma domain on NACHT NTPases containing ANKdc-protein was upregulated in *T. guizhouense* exclusively after contact with itself.

There are 6 ANKdc-proteins, that are upregulated in *T. guizhouense* exclusively after contact with *T. harzianum*. Among these, the most significantly upregulated ANKdc-protein contains a Protein kinase host-domain.

Table 10: RNA deepseq results from confrontation assays of *T. guizhouense* 4742. Confrontation with itself, *T. harzianum* 916 and *Fusarium oxysporum* Foc4. Protein IDs that are marked red belong to the core *Trichoderma* ANKyrome.

#### 4.4.2 Differential Gene Expression results from *T. harzianum* TUCIM 916

The search for ANKdc-proteins in DGE results from *T. harzianum* TUCIM 916 transcriptomic analysis are summarized in Table 11. All three confrontation assays led to common transcriptional response in *T. harzianum* by upregulation of expression of eight ANKdc-proteins in total. Five of these ANKdc-proteins were loner-ANKdc-proteins, of which jgi479222 was most significantly upregulated, especially in confrontations with self and with *T. guizhouense*. The rest of the ANKdc-proteins that were upregulated in *T. harzianum* in each confrontation assay were Sigma domain on NACHT-NTPases containing ANKdc-protein, PLNTH- and NP-domain containing ANKdc-protein, as well as the most strongly upregulated von Willebrand factor, type A domain containing ANKdc-protein.

Three ANKdc-proteins were upregulated in *T. harzianum* during the confrontation assay with itself and with *T. guizhouense*. Only two ANKdc-proteins, one loner- and one NP-domain containing ANKdc-proteins were upregulated only after contact with *T. guizhouense* and *F. oxysporum*.

Three ANKdc-proteins were upregulated exclusively after contact with *T. guizhouense*, one loner-ANKdc-protein, one NACHT domain containing ANKdc-protein and one NWD NACHT-NTPase domain containing ANKdc-protein. A PLNTH containing ANKdc-protein was upregulated exclusively in confrontation with *F. oxysporum*. In *T. harzianum* during confrontation with itself, the expression of a WD40- repeat and NP-domain containing ANKdc-protein was upregulated. Also, during the confrontation with itself three different loner-ANKdc-proteins were downregulated in *T. harzianum*.

ProteinID <i>T. harzianum</i>	Host-Domain Annotations	self	4742	Foc4

jgi270473	Sigma domain on NACHT-NTPases	2,72	2,63	2,1
jgi335626	P-loop containing nucleoside triphosphate hydrolase	2,1	2,09	2,27
	NACHT domain,			
jgi476900	ANK-domain	4,15	3,97	2,09
<b>jgi479222</b>	<b>ANK-domain</b>	<b>6,96</b>	<b>6,14</b>	<b>4,59</b>
jgi70585	ANK-domain	2,06	2,26	2,38
jgi551129	ANK-domain	2,65	2,57	3,25
jgi505476	von Willebrand factor, type A	5,29	4,61	3,62

Table 11: RNA deepseq results from confrontation assays of *T. harzianum* 916. Confrontation with *self*, *T. guizhouense* 4742 and *Fusarium oxysporum* Foc4. Protein IDs that are marked red belong to the core *Trichoderma* ANKyrome.

According to the DGE results, ANKdc-proteins predominantly have a function that is not linked to the interactions with other *Trichoderma* spp. and *Fusarium oxysporum* based on data obtained from Zhang, Miao, Rahimi, Shen, Druzhinina, unpublished.

## 5 Concluding remarks

The ANKdc-gene expansion was confirmed in strongly opportunistic *Trichoderma* spp. It has been also shown that this expansion is not exclusive to *Trichoderma* spp. In total 2406 ANKdc-proteins were mined from 10 *Trichoderma* spp., and eight genomes of closely related NTHGs. *T. virens* had the largest ANKyrome with 194 ANKdc-proteins, while *T. reesei* with 83 ANKdc-proteins had the smallest ANKyrome. ANK-repeats were re-annotated by InterProScan within Blast2GO software in *Trichoderma* ANKyrome using three databases, Pfam, SMART and Prosite. No specific pattern was observed in the location of ANK-domains in ANKdc-proteins or where they occur in genes (N-terminal, C-terminal or Mid-section) in association with other domains. Additionally, all associated host-domains were annotated by the same approach but using 14 available databases in InterProScan. *T. virens* had the smallest share of hdc-ANKdc-proteins, while the largest share of hdc-ANKdc-proteins was present in *T. guizhouense*. This study also revealed that two most frequent host-domains in *Trichoderma* ANKyrome were P-loop containing nucleoside triphosphate hydrolase (PLNTH) and nucleoside phosphorylase (NP), but also that majority of ANKdc-proteins with these host-domains were orphans.

OrthoFinder orthology inference found 1172 homologous proteins distributed between 183 orthogroups of which 18 were identified as core for *Trichoderma* spp. and 11 as core to all considered fungi from the taxonomical order Hypocreales. In most Hypocreales species the larger share of their respective ANKyrome consisted of orphan ANKdc-proteins. Phylogenetic analysis of 18 *Trichoderma* spp. core ANKdc-proteins resulted in tree topologies that were congruent with the multilocus tree without any deviations. Selection pressure analyses of the same core ANKdc-proteins using HyPhy methods BUSTED, MEME and FUBAR confirmed a significant ( $p < 0.05$  and  $P > 0.95$ ) purifying selection acting across all of 18 core ANKdc-proteins.

The trends demonstrated in the *Trichoderma* ANKyrome cannot be explained, until the purpose of these proteins is understood in more detail. Potential transformation candidates from transcriptomic data analysis were identified but generally most of ANKdc-proteins were not differentially expressed in confrontation assays with other fungi, so an alternative function must be proposed and tested.

The high abundance of orphans in *Trichoderma* ANKYrome suggest occurrence of evolutionary mechanisms such as segmental duplications and lateral gene transfer (LGT) events by which these genes may have originated. Horizontal gene transfer between Prokaryotes and Eukaryotes as one of the gene expansion mechanisms has been suggested first by (Bork 1993), but later questioned by (Al-Khodor *et al.* 2010), who suggested that expansion of ANKdc-genes probably occurred by gene duplication and convergent evolution. Their hypothesis is based on the fact that genes containing repeats are generally more prone to such mechanisms (Lynch and Conery 2000), but also that ANK-repeats interact with universal proteins in nature.

Recently, Druzhinina *et al.* described LGT of plant cell wall degradation enzymes from a wide range of phytopathogenic Ascomycota to *Trichoderma* which parasitizes on them. In this study it was suggested that LGT could have been assisted by adelphoparasitism of *Trichoderma*, meaning that *Trichoderma* spp. can prey on *Fusarium* spp. and even other *Trichoderma* (Druzhinina *et al.* 2018). Based on the findings from this thesis it cannot be concluded whether the orphan ANKdc-genes were obtained by means of convergent evolution or HGT. The most probable hypothesis is that these genes originated by a combination of multiple mechanisms. Further research is necessary to investigate these possibilities.

Mercer, Fleming, and Ueda found in 2005 that majority of ANKdc-proteins in poxvirus contain an F-box like domain. They suggested that ANK-domains selectively bind a certain protein and thereby directs the ubiquitination of this protein driven by F-box-like domains. Furthermore, since a wide range of ANKdc-proteins containing an F-box-like domain were found in poxvirus they proposed that their purpose is to degrade different host-proteins during viral infection. In *Trichoderma* only one protein of this kind was identified but it would be interesting to observe the effect of a knock-out of this protein on species parasitism.

In general, a similar assumption as with F-box containing ANKdc-proteins can be made with PLNTHs. These domains release energy from NTPs that could be used by a protein bound by ANK-domain. This could explain the presence of a high number of these proteins in *Trichoderma* spp. The transcriptomic data indicated an important role of PLNTHs containing ANKdc-proteins in mycoparasitism, but this can be confirmed only by specifically designed experiments.

Finally, the selection pressure analysis of core ANKdc-proteins indicate that they have a key function in *Trichoderma* interactomes that is maintained by purifying selection.

## 6 Outlook

In this thesis, only the core *Trichoderma* ANKyrome was used for selection pressure analysis, while selection pressure analysis of other ANKdc-proteins was outside the scope of this study. A complete phylogenetic analysis as well as selection pressure would give a deeper insight into the evolution of these proteins, especially the orphan ANKdc-proteins. Since the majority of *Trichoderma* ANKyrome was probably obtained by a mechanism different from vertical evolution, a horizontal gene transfer (HGT) analysis such as NOTUNG (which also points out duplication events) of orphan ANKdc-proteins could be included in a complete evolutionary analysis.

The most common host-domains in ANKdc-proteins in *Trichoderma* spp., the NP and PLNTH were predominantly found in orphan ANKdc-proteins. Proteins containing these domains are mostly involved in energy release from NTPs and they could be a good starting point for the evolutionary analysis of orphan ANKdc-proteins because of their disproportionate abundance. Transcriptomics data revealed that the majority of the *Trichoderma* ANKyrome is not differentially expressed during confrontation studies with other fungi, but a few potential knock-out candidates in *T. guizhouense* and *T. harzianum* both from their core and non-core ANKyromes have been identified. A deeper investigation by knock-out of these ANKdc-proteins, could provide us with more concrete information on the role of ANKdc-proteins in *Trichoderma*.

Furthermore, confrontation studies of *Trichoderma* spp. with certain mycoviruses, bacteria, and plants followed by transcriptomic analysis could potentially reveal a different ANKyrome expression profile. A more recent study identified a protein Caiap (CARD and ANK domains) with a 16 C-terminal ANK-domain, which acts as an adaptor protein for inflammasome-dependent resistance to *Salmonella enterica* infection of zebra fish (Tyrkalska *et al.* 2017). Even though this study was performed on zebra fish, it supports the idea of performing confrontation studies with bacteria to investigate the transcriptional response in *Trichoderma* spp. when in contact with certain bacterial species.

## 7 Curriculum Vitae

### Vladimir Gojic

Vienna, Austria

vladimir.gojic@gmail.com

21.08.1992, Teslic (Bosnia and Herz.)

#### EDUCATION

---

Oct 2016 – Jul 2018	<b>Master's degree - Technical Chemistry- Biotechnology, TU Wien</b>  <i>Master thesis:</i> "Convergent evolution of proteins with ankyrin domains the main genomic hallmark of an industrially relevant fungus <i>Trichoderma</i> ", Prof. I. Druzhinina research group"
Jul - Aug 2017	Optional Internship - Bioorganic synthesis  Co-Author - Publication ChemCatChem, Prof. M.D. Mihovilovic research group ( <a href="https://onlinelibrary.wiley.com/doi/full/10.1002/cctc.201800272">https://onlinelibrary.wiley.com/doi/full/10.1002/cctc.201800272</a> )  "Chemoenzymatic cascade reaction for the synthesis of enantiopure alcohols"
Aug - Sep 2017	Optional Internship - Optimization of industrial antibody production in CHO cells  Prof. Christoph Herwig research group  "Two-compartment scale-down model of fed-batch CHO cell culture"
Oct 2012 – Sep 2016	<b>Bachelor's degree - Technical Chemistry, TU Wien - BSc degree</b>  <i>Bachelor thesis:</i> "Chemoenzymatic one-pot cascade reaction for the production of enantiopure alcohols", Prof. M.D. Mihovilovic research group
Sep 2009 – Jun 2012	Secondary school BRG Rosasgasse, Vienna
Sep 2007 – Jun 2009	Secondary school BRG Jovan Ducic, Teslic, Bosnia and Herz.

#### WORK EXPERIENCE

---

Jul - Sep 2014	Baxter (today Shire), Vienna  Internship Quality Control
----------------	--

#### ADDITIONAL

---

Languages	Serbo-croatian (native), german (fluent) und english (fluent)
PC-skills	Python Basics, AutoCAD Basics, MS Office (VBA Basics)
