Kurzfassung

Im ersten Teil der Arbeit wurden die Komplexe $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{N}i\text{Pr}-\text{PPh}_2)]$, $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{N}t\text{Bu}-\text{PPh}_2)]$ und $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NCy}-\text{P}i\text{Pr}_2)]$ mit den Amidophosphin Liganden $\text{Li}[\text{R}_2\text{PNR}']$ ($\text{R} = \text{Ph}$, $i\text{Pr}$, $\text{R}' = i\text{Pr}$, $t\text{Bu}$, Cy) hergestellt. Diese Komplexe besitzen einen viergliedrigen Carboxyamido-phosphazyklus, welche durch einen nucleophilen Angriff von Stickstoff auf den Kohlenstoff der Carbonylgruppe entsteht. Wenn diese Komplexe mit dem Elektrophil $[\text{Me}_3\text{O}]\text{BF}_4$ umgesetzt werden, entsteht ein Aza-phospha-carbenkomplex vom Typ $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})=\text{C}(\text{OMe})-\text{N}i\text{Pr}-\text{PPh}_2)]^+$. Durch Umsetzung der Komplexe *cis,trans,cis*- $[\text{Fe}(\text{Ph}_2\text{PNH}i\text{Pr})_2(\text{CO})_2(\text{Br})_2]$ und *cis,trans,cis*- $[\text{Fe}(\text{Ph}_2\text{PNH}t\text{Bu})_2(\text{CO})_2(\text{Br})_2]$ mit $\text{KO}t\text{Bu}$ entstehen ebenfalls Verbindungen mit einem viergliedrigen Carboxyamido-phosphazyklus, wie zum Beispiel *trans*- $[\text{Fe}(\text{Ph}_2\text{PNH}i\text{Pr})(\text{CO})_2(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{N}i\text{Pr}-\text{PPh}_2)\text{Br}]$ und *trans*- $[\text{Fe}(\text{Ph}_2\text{PNH}t\text{Bu})(\text{CO})_2(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{N}t\text{Bu}-\text{PPh}_2)\text{Br}]$.

Im zweiten Teil der Arbeit wurden die oktaedrischen $\text{Mo}(0)$ und $\text{W}(0)$ Komplexe $[\text{M}(\text{PNP})(\text{CO})_3]$, sowie die oktaedrischen neutralen und siebenfach-koordinierten kationischen $\text{Mo}(\text{II})$ und $\text{W}(\text{II})$ Komplexe $[\text{M}(\text{PNP})(\text{CO})\text{X}_2]$, $[\text{M}(\text{PNP})(\text{CO})_3\text{Br}]^+$, $[\text{M}(\text{PNP})(\text{CO})_3\text{H}]^+$ mit dreizähligen PNP Pincer Liganden hergestellt ($\text{X} = \text{Br}$, I und Cl). Die Synthese von $\text{Mo}(0)$ Komplexen erfolgte durch Umsetzung von $[\text{Mo}(\text{CO})_3(\text{CH}_3\text{CN})_3]$ mit PNP Liganden. Die $\text{W}(0)$ Komplexe wurden durch die Reduktion von den Komplexen $[\text{W}(\text{PNP})(\text{CO})_3\text{Br}]^+$ mit NaHg hergestellt, welche durch Umsetzung vom zweikernigen Komplex $[\text{W}(\text{CO})_4(\mu-\text{Br})\text{Br}]_2$ mit den PNP Liganden hergestellt wurden. Die Synthese von den Hydridocarbonylkomplexen erfolgte durch Umsetzung von den $\text{Mo}(0)$ und $\text{W}(0)$ Komplexen mit HBF_4 . Diese Komplexe sind in der Lösung dynamisch und können mit Basen, z.B. NEt_3 , vollständig zu $[\text{M}(\text{PNP})(\text{CO})_3]$ deprotoniert werden. Wenn die $\text{Mo}(0)$ Komplexe mit Halogenen in Anwesenheit des Sauerstoffs umgesetzt werden, entstehen kationische Monooxo-Molybdänkomplexe vom Typ $[\text{Mo}(\text{PNP})(\text{O})\text{X}]^+$. Diese Reaktion verläuft über koordinativ ungesättigte mono CO Komplexe $[\text{M}(\text{PNP})(\text{CO})\text{X}_2]$.

Abstract

In first part of this study the complexes $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{N}i\text{Pr}-\text{PPh}_2)]$, $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{N}t\text{Bu}-\text{PPh}_2)]$ and $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NCy}-\text{P}i\text{Pr}_2)]$ were produced with adding 1 equiv of the amidophosphine ligands $\text{Li}[\text{R}_2\text{PNR}']$ ($\text{R} = \text{Ph}, i\text{Pr}, \text{R}' = i\text{Pr}, t\text{Bu}, \text{Cy}$) to $[\text{FeCp}(\text{CO})_2\text{Cl}]$. Complex $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{N}i\text{Pr}-\text{PPh}_2)]$ was also formed when $[\text{FeCp}(\text{PPh}_2\text{NH}i\text{Pr})(\text{CO})_2]^+$ was reacted with 1 equiv of $\text{KO}t\text{Bu}$. These complexes feature an unusual four-membered carboxamido-phospha-ferracycle as a result of an intramolecular nucleophilic attack of the amidophosphine ligand on coordinated CO. Upon treatment of $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{N}i\text{Pr}-\text{PPh}_2)]$ with the electrophile $[\text{Me}_3\text{O}]\text{BF}_4$ the aminocarbene complex $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})=\text{C}(\text{OMe})-\text{N}i\text{Pr}-\text{PPh}_2)]^+$ was obtained bearing an aza-phospha-carbene moiety. Upon treatment of *cis,trans,cis*- $[\text{Fe}(\text{Ph}_2\text{PNH}i\text{Pr})_2(\text{CO})_2(\text{Br})_2]$ and *cis,trans,cis*- $[\text{Fe}(\text{Ph}_2\text{PNH}t\text{Bu})_2(\text{CO})_2(\text{Br})_2]$ with $\text{KO}t\text{Bu}$ the carboxamido-phospha-ferracycles *trans*- $[\text{Fe}(\text{Ph}_2\text{PNH}i\text{Pr})(\text{CO})_2(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{N}i\text{Pr}-\text{PPh}_2)\text{Br}]$ and *trans*- $[\text{Fe}(\text{Ph}_2\text{PNH}t\text{Bu})(\text{CO})_2(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{N}t\text{Bu}-\text{PPh}_2)\text{Br}]$ were formed.

In the second part a series of Mo(0) and W(0) complexes $[\text{M}(\text{PNP})(\text{CO})_3]$ as well as seven coordinate cationic hydridocarbonyl and halocarbonyl Mo(II) and W(II) complexes of the type $[\text{M}(\text{PNP})(\text{CO})_3\text{H}]^+$ and $[\text{M}(\text{PNP})(\text{CO})_3\text{X}]^+$ and octahedral neutral $[\text{Mo}(\text{PNP})(\text{CO})\text{X}_2]$ featuring PNP pincer ligands were prepared. The synthesis of Mo(0) complexes $[\text{Mo}(\text{PNP})(\text{CO})_3]$ was accomplished by treatment of $[\text{Mo}(\text{CO})_3(\text{CH}_3\text{CN})_3]$ with the respective PNP ligands. The analogous W(0) complexes were prepared by reduction of the bromocarbonyl complexes $[\text{W}(\text{PNP})(\text{CO})_3\text{Br}]^+$ with NaHg. These intermediates were obtained from the known dinuclear complex $[\text{W}(\text{CO})_4(\mu-\text{Br})\text{Br}]_2$, prepared in situ from $\text{W}(\text{CO})_6$ and stoichiometric amounts of Br_2 . Addition of HBF_4 to $[\text{M}(\text{PNP})(\text{CO})_3]$ resulted in clean protonation at the molybdenum and tungsten centers to generate cationic Mo(II) and W(II) hydride complexes $[\text{M}(\text{PNP})(\text{CO})_3\text{H}]^+$. The protonation is fully reversible and upon addition of NEt_3 as base the Mo(0) and W(0) complexes $[\text{M}(\text{PNP})(\text{CO})_3]$ are regenerated quantitatively. All heptacoordinate complexes exhibit fluxional behavior in solution. Treatment of Mo(0) complexes with halogens in the presence of oxygen afforded cationic monooxo complexes of the type $[\text{Mo}(\text{PNP})(\text{O})\text{X}]^+$. This Reaction proceeds via the Mo(II) intermediates $[\text{Mo}(\text{PNP})(\text{CO})\text{X}_2]$.

Mein Dank gilt

Prof. Kirchner für die Unterstützung bei der Umsetzung eigener Ideen, für viele Anregungen und interessante Diskussionen und die Freude an der Chemie, die er allen vermittelt und für die Durchführung der DFT Berechnungen, die meine Arbeit bereichert haben.

Prof. Mereiter für die Durchführung vieler Röntgenstrukturanalysen und die vielen wissenschaftlichen und auch nichtwissenschaftlichen Diskussionen.

Prof. Weil und Dr. Stöger für die Durchführung von Röntgenstrukturanalysen.

Dr. Puchberger für die Durchführung von Tieftemperatur-NMR Messungen.

Dr. Sven Barth für die gute Freundschaft.

Meine Kollegen DI Christian Holzacker, DI Bernhard Bichler, DI Nikolaus Gorgas, Mathias Glatz und Matthias Mastalir für die gute Zusammenarbeit.

Meinen Eltern und meinen Schwestern für ihr Verständnis und ihre Unterstützung.

Allgemeiner Teil

Einleitung und Problemstellung (Eisenkomplexe)

Aminophosphinliganden $\text{PR}_2\text{NHR}'$ sind multifunktionelle Liganden mit einer polaren P(III)-N Bindung und werden häufig als vielseitige Liganden für Übergangsmetalle verwendet.¹ Für die Synthese werden primäre oder sekundäre Amine und PR_2Cl verwendet. Um sterischen und elektronischen Eigenschaften zu variieren, können die Liganden durch Alkyl oder Arylgruppen beliebig modifiziert werden. Wegen der „soft/hard“ Atomkombination und dem aciden NH zeigen diese Liganden eine Vielzahl von unterschiedliche Koordinationsmöglichkeiten (Schema 1).

Schema 1: Häufige Koordinationsmöglichkeiten von $\text{PR}_2\text{NHR}'$ -Liganden

Bei mittleren und späten Übergangsmetallen findet man in der Regel eine $\kappa^1(P)$ -Koordination (**I**). Bei deprotonierten $\text{PR}_2\text{NHR}'$ Liganden findet man eine $\kappa^1(P,N)$ (**III**) und $\kappa^1(N)$ (**II**) Koordination (Schema 1). In Kombination mit frühen und späten Übergangsmetallen gibt es μ^2 -gebrückte Komplexe vom Typ (**IV**).^{3,4}

Überdies zeigen $\text{PR}_2\text{NHR}'$ Liganden eine Vielzahl von intramolekularen Reaktionen. Vinyliden und Allenyliden Ruthenium Komplexe vom Typ $[\text{RuCp}(\text{PPh}_2\text{NHR})_2(=\text{C}=(\text{C})_n=\text{CHR}')]^+$ und $[\text{RuTp}(\text{PPh}_2\text{NHR})_2(=\text{C}=(\text{C})_n=\text{CHR}')]^+$ ($n = 0, 1$; $\text{R} = \text{Ph}, n\text{-Pr}$; $\text{R}' = \text{alkyl, aryl}$), kommt es zu einer intramolekularen Addition von NHR' an den α -Kohlenstoff und es bildet sich ein viergliedriges Aza-phospha-carben (Schema 2, 3, **A**).⁵

Schema 2: Intramolekulare Addition von NHR' am α -Kohlenstoff

Weiters gibt es einige Amidobutadienkomplexe vom Typ $[\text{RuCp}(\text{PPh}_2\text{NHPH})(\text{CH}_3\text{CN})_2]^+$ und $[\text{RuCp}^*(\text{PR}_2\text{NHR}')(\text{CH}_3\text{CN})_2]^+$ ($\text{R} = \text{Ph}, i\text{-Pr}, \text{R}' = \text{Ph}, \text{C}_6\text{F}_5$), wo die $\text{PR}_2\text{NHR}'$ Liganden intramolekulare Reaktionen mit dem Butadienfragment und auch dem Metall eingehen (Schema 3, **B**).⁶

Schema 3: Unterschiedliche Metalle mit einem viergliedrigen Aminophosphinering.

Bunten *et al* haben dinukleare Ruthenium Komplexe $[\text{Ru}_2(\text{CO})_3(\mu^2\text{-PPh}_2)(\mu^2\text{-Ph}_2\text{PNMePPh}_2)(\kappa^2(\text{C},\text{P})\text{-C(=O)NMePPh}_2)]$ mit Carboxamido-phospharutheniumringen veröffentlicht (Schema 3, **C**).⁷ Heberhold und Mitarbeiter berichteten über die Synthese der Halbsandwichkomplexe $[\text{MCp}(\text{CO})_2(\text{C(=O)N(S-NHP}t\text{Bu}_2)]$ ($\text{M} = \text{Cr}, \text{Mo}, \text{W}$).⁸

Für Eisen findet man einen Hydrazinophosphin Komplexe $[\text{FeCp}(\text{PPh}_2\text{NHNMe}_2)(\text{CO})_2]^+$, welcher ähnlich den $\text{PR}_2\text{NHR}'$ -Liganden reagiert. Die Reaktion dieses Komplexes mit $n\text{-BuLi}$ liefert einen Carboxamido-phospha-ferrazyklus $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})\text{-C(=O)-NNMe}_2\text{-PPh}_2)]$ (Schema 3, **D**).⁹

In der folgenden Arbeit sollten neue Eisenkomplexe mit $\text{PR}_2\text{NHR}'$ -Liganden dargestellt werden und deren Reaktivität näher untersucht werden.

Einleitung und Problemstellung (Molybdän und Wolfram Komplexe)

Dreizählige PNP Liganden mit $-CH_2PR_2$ Substituenten in den *ortho* Positionen eines Pyridinringes, sogenannte Pincer Liganden, haben große Verwendungen bei den Übergangsmetallen (Fe, Ru, Rh, Ir, Pd, Pt).¹²⁻²¹ Analoge PNP Liganden mit $NHPR_2$ Substituenten sind wesentlich seltener. Ein erstes Beispiel wurde von Schirmer entwickelt (PNP-Ph).²² Viele Komplexe mit unterschiedlichen Übergangsmetallen (Ni(II), Pd(II), Pt(II), Fe(II)) und mit unterschiedlichen PNP Pincer-Liganden ($-NR'PR_2$ mit $R' = H, \text{alkyl}$, $R = \text{alkyl, aryl}$), bei denen die sterische, elektronische und stereochemische Eigenschaften einfach und modular geändert werden können, wurden von unserer Gruppe veröffentlicht (Schema 4).²⁴⁻²⁷

Schema 4: Beispiele von Übergangsmetallkomplexen mit PNP Pincer-Liganden.

In Bezug auf Molybdän und Wolfram findet man überraschenderweise wenige Beispiele von PNP Pincerkomplexen. Walton und Mitarbeiter haben einen dinuclearen Molybdänkomplex $(Mo(PNP)Cl)Mo(HPCy_2)Cl_3$ (PNP = 2,6-bis-(dicyclohexylphosphinomethyl)pyridin) publiziert (Schema 5).²⁸

Schema 5: $Mo(PNP)(Cl)Mo(HPCy_2)Cl_3$.

Vor einigen Jahren wurde ein Distickstoffmolybdänkomplex von Arashiba in publiziert.²⁹ Dieser Komplex ist in der Lage Stickstoff zu aktivieren und wurde als Katalysator zur Herstellung von Ammoniak verwendet (Schema 6). Bei dieser Reaktion wurde Cobaltocen als Reduktionsmittel und protoniertes 2,6-Dimethylpyridin als Protonenquelle verwendet.

Schema 6: Beispiel eines Distickstoffmolybdänkomplexes und die katalytische Bildung von Ammoniak.

In jüngster Zeit hat Templeton die Synthese von Hydridocarbonyl und Halocarbonyl Wolframkomplexen mit PNP-Pincerliganden vom Typ $\text{HN}(\text{SiMe}_2\text{CH}_2\text{PPh}_2)_2$ veröffentlicht (Schema 7).³⁰

Schema 7: Darstellung von Hydridocarbonyl und Halocarbonyl Wolframkomplexe.

In der folgenden Arbeit sollten neue Molybdän und Wolfram Komplexe mit PNP Pincer Liganden dargestellt werden und deren Reaktivität soll näher untersucht werden.

1. Synthese der Liganden

1.1. Einzählige PN-Liganden

- 1a R = Ph, R' = *i*Pr
- 1b R = Ph, R' = *t*Bu
- 1c R = Ph, R' = *n*Pr
- 1d R = *i*Pr, R' = *i*Pr
- 1e R = *i*Pr, R' = Toluidin
- 1f R = *i*Pr, R' = ^oHex.

Schema 8: Herstellung der PN-Liganden

Die Synthese von Liganden $\text{R}_2\text{PN}(\text{H})\text{R}'$ (**1a-f**) erfolgte durch Umsetzung von R_2PCl mit zwei Äquivalenten von $\text{H}_2\text{NR}'$ in Et_2O bei 30°C (Schema 8). Die Charakterisierung wurde mittels ^1H , $^{13}\text{C}\{^1\text{H}\}$ und $^{31}\text{P}\{^1\text{H}\}$ NMR Spektroskopie gemacht (Tabelle 1).

1.2. Dreizählige PNP-Liganden

Die Synthese von PNP-Ph (**2a**), PNP-*i*Pr (**2b**) und PNP-*t*Bu (**2c**) wurde in der Literatur^{10,11} beschrieben.

1.2.1. Synthese von $\text{PNP}^{\text{Me}}\text{-iPr}$

Bei Komplexen spielen die elektronischen und sterischen Eigenschaften von Liganden eine große Rolle. Um die geeignete Kombination von den beiden Effekten zu finden, sollten die Liganden modifiziert werden. Es gibt mehrere Möglichkeiten diese Modifikationen durchzuführen. Eine Möglichkeit ist Substituenten am Pyridinring einzuführen. Eine weitere Möglichkeit ist Variation der PR_2 Gruppe. Die Möglichkeit die hier gewählt wurde ist die Einführung von Substituenten an der NH Gruppe (Schema 9).

Schema 9: Herstellung des PNP^{Me}-Liganden

Nach dem Schützen des Phosphors von **2b** wurde **2b·BH₃** mit 2 Äquivalenten *n*BuLi deprotoniert und mit Methyljodid umgesetzt. Danach wurde **2d·BH₃** in siedendem Diethylamin entschützt. Das Produkt wurde mittels ¹H, ¹³C{¹H} und ³¹P{¹H} NMR Spektroskopie charakterisiert (Tabelle 1).

Tabelle 1: ³¹P{¹H} NMR Signale (ppm) der verschiedenen PN und PNP Liganden (δ, 25 °C, CDCl₃, bezogen auf H₃PO₄ (85%))

Ph ₂ PN/ <i>i</i> Pr 1a	Ph ₂ PN/ <i>t</i> Bu 1b	Ph ₂ PN/ <i>n</i> Pr 1c	<i>i</i> Pr ₂ PN/ <i>i</i> Pr 1d	<i>i</i> Pr ₂ PN/toluidin 1e

69.9	37.7	60.0	70.5	88.5

2-Eisenkomplexe mit einzähnigen PN Liganden

2.1 $\text{Fe}(\text{R}_2\text{PNHR}')_2(\text{CO})_2\text{Br}_2$ 

Schema 10: Herstellung der $\text{Fe}(\text{R}_2\text{PNHR}')_2(\text{CO})_2\text{Br}_2$ -Komplexe

Die Komplexe (Schema 10) wurden durch Umsetzung von $\text{Fe}(\text{CO})_4\text{Br}_2$ mit 2 Äquivalenten $\text{R}_2\text{PNHR}'$ hergestellt. Die zwei CO und Br Gruppen stehen *cis* zueinander wogegen die PN-Liganden *trans* zueinander stehen. Die Komplexe wurden mittels ^1H , $^{13}\text{C}\{^1\text{H}\}$, $^{31}\text{P}\{^1\text{H}\}$ NMR und IR charakterisiert (Tabelle 2). Im IR Spektrum findet man für die CO Liganden zwei Banden, symmetrische und asymmetrische Streckenschwingung, im Bereich von $2040 - 1979 \text{ cm}^{-1}$. Die beiden Phosphoratome sind chemisch äquivalent und man findet deshalb nur ein Singulett im $^{31}\text{P}\{^1\text{H}\}$ NMR Spektrum bei 72.2, 80.6 und 82.3 ppm (*t*Bu, *i*Pr und *n*Pr). Im $^{13}\text{C}\{^1\text{H}\}$ NMR findet man ein Triplett für die beiden Carbonylliganden im Bereich 212.7 und 213.3 ppm.

2.2 $[\text{Fe}(\text{R}_2\text{PNHR}')(\text{CO})_2(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NR}'-\text{PR}_2)]$ 

Schema 11: Herstellung der $[\text{Fe}(\text{R}_2\text{PNHR}')(\text{CO})_2(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NR}'-\text{PR}_2)]$ Komplexe

Die Reaktion erfolgte durch Umsetzung von **3a** und **3b** mit KO*t*Bu unter CO Atmosphäre in THF bei Raumtemperatur (Schema 11). Die Ausbeuten liegen zwischen 40 und 50%. Deprotonierung lieferte einen viergliedrigen Carboxyamido-phosphazyklus durch eine intramolekularen nucleophilen Angriff auf einen Carbonyl-Kohlenstoff. Im Fall von **3a** entstehen zwei Isomere im Verhältnis 5:1. Bei Komplex **3d**, welcher laut DFT/B3LYP Berechnungen energetisch günstiger ist, stehen die CO Gruppen zueinander *cis* und bei **3d'** *trans* (Abbildung 1). Die Komplexe wurden mittels ^1H -, $^{13}\text{C}\{^1\text{H}\}$ -, $^{31}\text{P}\{^1\text{H}\}$ NMR und Einkristall Röntgendiffraktion charakterisiert (Abbildung 2, Tabelle 2).

Abbildung 1: Optimierte (DFT/B3LYP) Strukturen von **3d** und **3d'**

Im $^{13}\text{C}\{^1\text{H}\}$ NMR Spektrum gib es ein Triplett für zwei die CO Gruppen bei 212.4 ppm mit einer P-C Kopplungskonstante J_{PC} von 22.7 Hz und für die Carboxyamido Einheit ein dublettisches Dublett bei 206.0 ppm mit Kopplungskonstanten J_{PC} von 9.6 und 13.4 Hz. Im $^{31}\text{P}\{^1\text{H}\}$ NMR gibt es zwei Dubletts bei 95.6 und 85.8 ppm mit einer Kopplungskonstante von 84.7 Hz, welche klar Zeigt, dass die beiden P-Atome in *trans* Position zueinander stehen. Im IR Spektrum findet man die erwarteten zwei Banden für die CO Liganden bei 1955 und 1950 cm^{-1} und für die Carboxyamido Gruppe bei 1619 cm^{-1} . Die Daten von Komplex **3e** sind ähnlich wie die von **3d**.

Abbildung 2: ORTEP Diagram von $[\text{Fe}(\text{R}_2\text{PNHR}')(\text{CO})_2(\kappa^2(\text{C},\text{P})\text{-}(\text{C}=\text{O})\text{NR}'\text{PR}_2)]$ (**3d**) mit Bindungslängen und Winkeln (\AA , $^\circ$): Fe1–Br1 2.4752(6), Fe1–P1 2.2480(9), Fe1–P2 2.2651(9), Fe1–C33 1.799(3), Fe1–C32 1.826(3), Fe1–C31 1.997(3), P2–N2 1.650(3), P1–N1 1.694(3), C31–O1 1.221(4), C31–N1 1.409(4), P1–Fe1–C31 68.9(1), Fe1–P1–N1 85.3(1), Fe1–C31–O1 134.2(2), Fe1–C31–N1 103.6(2), O1–C31–N1 122.2(3), P1–N1–C31 101.5(2), P1–N1–C13 132.4(2), N2...O1 2.839(4).

Die Struktur von **3d** wurde mit kristallographisch bestimmt. Die Geometrie des Komplexes ist ein verzerrter Oktaeder. Die beide Phosphoratome und die beide CO Moleküle sind zueinander *trans* und das Brom steht *trans* zum Kohlenstoffatom der Carboxyamidogruppe. Der Winkel $\text{C}_{32}\text{-Fe}_1\text{-C}_{33}$ ist $170.6(2)^\circ$ und es gibt eine starke Wasserstoffbrückenbindung zwischen $\text{N}_2\text{-H}_{2\text{n}}$ und O_1 .

2.3 [FeCp(R₂PNHR')(CO)₂]X

Schema 12: Herstellung der [FeCp(R₂PNHR')(CO)₂]X –Komplexe

Die Komplexe wurden durch Umsetzung von FeCp(CO)₂X mit R₂PNHR' in THF hergestellt (Schema 12). Die entstandenen Komplexe sind kationisch und trigonal pyramidal. Die Charakterisierung erfolgte mittels ¹H, ¹³C{¹H}, ³¹P{¹H} NMR, IR und Einkristall Röntgendiffraktion (Abbildung 3, Tabelle 2). Im IR Spektrum gibt es zwei Banden für die CO Liganden, die klar zeigen das diese cis zu einander stehen (2043 – 1993 cm⁻¹). Im ³¹P{¹H} NMR Spektrum gibt es ein Singulett zwischen 91.1 und 136.2 ppm und im ¹³C{¹H} NMR gibt es für die zwei CO Liganden ein Dublett zwischen 209.9 und 212.4 ppm mit einer Kopplungskonstante J_{PC} von ca 27 Hz. Es gibt zwischen Br⁻ und H_{1n}-N₁ eine Wasserstoffbrückenbindung.

Abbildung 3: ORTEP Diagramm von $[\text{FeCp}(\text{R}_2\text{PNHR}')(\text{CO})_2]\text{X}$ (**3f**) mit Bindungslängen und Winkeln (\AA , $^\circ$): $\langle \text{Fe1}-\text{C}_{\text{Cp}} \rangle = 2.104(2)$, $\text{Fe1}-\text{P1}$ 2.2223(4), $\text{Fe1}-\text{C6}$ 1.780(2), $\text{Fe1}-\text{C7}$ 1.785(2), $\text{C6}-\text{O1}$ 1.141(2), $\text{C7}-\text{O2}$ 1.139(2), $\text{P1}-\text{N1}$ 1.6473(13), $\text{N1}-\text{C20}$ 1.477(2), $\text{P1}-\text{Fe1}-\text{C6}$ 90.73(5), $\text{P1}-\text{Fe1}-\text{C7}$ 93.83(5), $\text{C6}-\text{Fe1}-\text{C7}$ 96.28(7), $\text{C20}-\text{N1}-\text{P1}$ 125.14(10), $\text{N1}\dots\text{Br1}$ 3.3854(13).

2.4 $\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NR}'-\text{PR}_2)$

Schema 13: Herstellung der $\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NR}'-\text{PR}_2)$ Komplexe

Diese Produkte wurden durch Umsetzung von $\text{FeCp}(\text{CO})_2\text{Cl}$ mit deprotonierten $\text{PR}_2\text{NHR}'$ Liganden hergestellt (Schema 13). Es gibt einen nucleophilen Angriff vom basischen Amidostickstoff an die Carbonylgruppe und entsteht ein viergliedriger

Carboxyamido-phosphazyklus. Die Charakterisierung erfolgte mittels ^1H -, $^{13}\text{C}\{^1\text{H}\}$ - und $^{31}\text{P}\{^1\text{H}\}$ NMR (Abbildung 4, Tabelle 2). Im $^{31}\text{P}\{^1\text{H}\}$ NMR Spektrum gibt es ein Singulett 111.6 (**3k**), 113.0 (**3m**) und 140.0 ppm (**3l**) und es gibt im $^{13}\text{C}\{^1\text{H}\}$ NMR für den CO Ligand ein Dublett bei 220.9 (**3k**), 221.0 (**3l**) und 221.0 ppm (**3m**) mit P-C Kopplungskonstanten zwischen 24.4 und 26.4 Hz. Für die Kohlenstoffe von den Carboxyamidogruppen gibt es auch ein Dublett bei 200.4 ppm ($J_{PC} = 39.0$ Hz) (**3k**), 201.1 ppm ($J_{PC} = 45.8$ Hz) (**3m**) und 199.8 ppm ($J_{PC} = 37.8$ Hz) (**3n**). Im IR Spektrum gibt es eine Bande für CO im Bereich von 1937-1914 cm^{-1} und für die Carboxyamidogruppe im Bereich von 1618-1605 cm^{-1} .

Abbildung 4: ORTEP Diagramm von $\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NR}'-\text{PR}_2)$ (**3k**) mit Bindungslängen und Winkeln (\AA , $^\circ$): $\langle \text{Fe1}-\text{C}_{\text{Cp}} \rangle = 2.101(1)$, $\text{Fe1}-\text{P1}$ 2.1773(3), $\text{Fe1}-\text{C6}$ 1.739(1), $\text{Fe1}-\text{C7}$ 1.981(1), $\text{C6}-\text{O1}$ 1.158(2), $\text{C7}-\text{O2}$ 1.219(2), $\text{N1}-\text{C7}$ 1.404(2), $\text{P1}-\text{N1}$ 1.6915(10), $\text{C6}-\text{Fe1}-\text{P1}$ 69.01(4), $\text{Fe1}-\text{C7}-\text{O2}$ 133.8(1), $\text{Fe1}-\text{C7}-\text{N1}$ 103.7(1), $\text{Fe1}-\text{P1}-\text{N1}$ 86.95(3), $\text{P1}-\text{N1}-\text{C7}$ 99.7(1).

Anhand der Strukturanalyse zeigen diese Komplexe eine sogenannte „three legged piano stool“ Geometrie. Die Beine entstehen von P, C(CO) und C(=O).

Wenn diese Komplexe mit $[\text{Me}_3\text{O}]\text{BF}_4$ in CH_2Cl_2 umgesetzt werden, entstehen die viergliedrigen aza-phosphin Carbenkomplexe (Schema 13).

Schema 13: Herstellung der Komplexe **3i** und **3n**

Es entsteht **3i** durch eine ringöffnende Reaktion, wenn **3k** statt $[\text{Me}_3\text{O}]\text{BF}_4$ mit NH_4Cl umgesetzt wird. Der Carbenkomplex (**3n**) wurde mittels $^{13}\text{C}\{^1\text{H}\}$ NMR charakterisiert. Es gibt eine Verschiebung bei 238 ppm, welche mit literaturbekannten Fischer Carbenen übereinstimmen.

3. Molybdän und Wolfram Komplexe mit PNP Liganden

3.1. Synthese von $[M(\text{PNP-R})(\text{CO})_3\text{X}]\text{X}$ ($M = \text{Mo}, \text{W}, 18e^-$)

Schema 14: Herstellung der Komplexe **5a, b, e, f** und **g**

Diese Komplexe wurden durch Umsetzung der bekannten Verbindung $[\text{M}(\text{CO})_4(\mu\text{-Br})\text{Br}]_2$ ²³ mit PNP-R Liganden hergestellt (Schema 14). Die Komplexe sind kationisch und siebenfach koordiniert, deshalb zeigen die Komplexe eine verzerrte oktaedrische Struktur. Die Charakterisierung wurde mittels ^1H , $^{13}\text{C}\{^1\text{H}\}$, $^{31}\text{P}\{^1\text{H}\}$ NMR, IR und ein Kristall Röntgen Diffraktion gemacht (Tabelle 3, Abbildung 5 und 6). Im IR Spektrum gibt es drei CO Banden im Bereich von 2040-1875 cm^{-1} . In den $^{13}\text{C}\{^1\text{H}\}$ NMR Spektren gibt es zwei Triplets für die CO Gruppe mit einer Intensität von 1:2 im Bereich 234.6-191.3 ppm. Vom Komplex **5a** konnte wegen der schlechten Löslichkeit kein $^{13}\text{C}\{^1\text{H}\}$ NMR gemessen werden. Es gibt ein Singulett in den $^{31}\text{P}\{^1\text{H}\}$ NMR Spektren für jeden Komplex im Bereich von 85.2 – 131.6 ppm.

Abbildung 5: ORTEP Diagramm von $[W(\text{PNP-Ph})(\text{CO})_3\text{Br}]\text{Br}$ (**5e**) mit Bindungslängen und Winkeln (\AA , $^\circ$): W-C(31) 2.017(5), W-C(30) 2.020(6), W-C(32) 2.024(8), W-N(1) 2.237(3), W-P(1) 2.4955(10), W-P(2) 2.4895(11), W-Br(1) 2.6015(5); P(1)-W-P(2) 152.34(4), N(1)-W-P(1) 77.44(9), N(1)-W-P(2) 75.92(9), N(1)-W-C(30) 137.76(16), N(1)-W-C(31) 82.35(16), N(1)-W-C(32) 150.87(8), N(1)-W-Br(1) 82.28(9).

Die molekulare Struktur dieser Verbindung wurde mit Hilfe von Einkristall Röntgendiffraktion bestimmt. Zwei CO Gruppe liegen in der PNP Ebene und in *cis* Position zu einander. Die dritte CO Gruppe liegt in axialer Position und *trans* zum Br Atom. Im Wolframkomplex (**5e**) gibt es ein zweites Isomer (14%), bei dem es einen Austausch zwischen Br und C₃₂-O₃ gibt.

Abbildung 6: ORTEP Diagramm von $[\text{Mo}(\text{PNP-}i\text{Pr})(\text{CO})_3\text{Br}]\text{Br}$ (**5b**) mit Bindungslängen und Winkeln (\AA , $^\circ$): Mo-C(18) 2.037(2), Mo-C(19) 1.979(2), Mo-C(20) 2.006(2), Mo-N(1) 2.236(2), Mo-P(1) 2.5242(5), Mo-P(2) 2.5172(5), Mo-Br(1) 2.6713(3); P(1)-Mo-P(2) 150.80(2), N(1)-Mo-P(1) 75.67(4), N(1)-Mo-P(2) 75.35(4), N(1)-Mo-C(18) 85.95(7), N(1)-Mo-C(19) 77.73(6), N(1)-Mo-C(20) 127.23(6), N(1)-Mo-Br(1) 84.22(4).

3.2. Synthese von $\text{Mo}(\text{PNP}^{\text{Me-}i\text{Pr}})(\text{CO})\text{X}_2$

Schema 15: Herstellung der Komplexe **6a, b**

Die Synthese dieser Komplexe erfolgte durch Umsetzung von **4d** mit elementarem Iod oder Brom. Im Vergleich zu den Komplexen mit PNP-Ph, PNP-*i*Pr und PNP-*t*Bu Liganden entsteht ein oktaedrischer neutraler koordinativ ungesättigter Komplex (Schema 15). Diese Methode funktionierte nicht für Chlor, weil die Stöchiometrie schlecht kontrolliert werden kann und es zu Überoxidationen kam, was zu Bildung von paramagnetischen schwer abzutrennenden Nebenprodukten führte. Deshalb

erfolgte die Darstellung dieses Komplexes durch die Reaktion von $[\text{M}(\text{CO})_4(\mu\text{-Cl})\text{Cl}]_2$ ²³ mit $\text{PNP}^{\text{Me-}i\text{Pr}}$ gemäß Schema 16.

Schema 16: Herstellung von Komplex **6c**

Die Charakterisierung erfolgte mittels ^1H , $^{13}\text{C}\{^1\text{H}\}$, $^{31}\text{P}\{^1\text{H}\}$ NMR, IR und Einkristall Röntgendiffraktion (Tabelle 3, Abbildung 8a, 8b, 9, und 10). Das Molekül ist ein verzerrter Oktaeder. Das Molybdänatom liegt signifikant über der PNP Ebene. Der Winkel zwischen $\text{P}_1\text{-Mo-P}_2$ ist ungefähr 128° . Die Liganden X (X= Cl, Br, I) und CO in der axiale Position stehen zu einander *trans* und ein zweites X Atom steht *trans* zum Stickstoff im Pyridinring (Abbildung 8a, 8b, 9, 10). Die Komplexe sind diamagnetisch, weil die $2e_g$ und t_{2g} Orbitale energetisch unterschiedlich sind. Außerdem sind die Komplexe sehr stabil, weil die leere LUMO, LUMO+1 und LUMO+2 Orbitale in der PNP-R Ebene liegen. Metall ist sterisch schlecht für einen Angriff zugänglich (Abbildung 7).

Abbildung 7: HOMO und LUMO Orbitale von **6a**, **b** und **c**

Der zweite Grund der Stabilität dieser Verbindungsklasse liegt darin, dass Mo Atom von den Liganden sterisch abgeschirmt ist (Abbildung 8a).

Abbildung 8a: Spacefilling Model von $[\text{Mo}(\text{PNP}^{\text{Me-}/\text{iPr}})(\text{CO})\text{Cl}_2]$ (**6c**)

Abbildung 8b: ORTEP Diagramm von $[\text{Mo}(\text{PNP}^{\text{Me-}i\text{Pr}})(\text{CO})\text{Cl}_2]$ (**6c**) mit Bindungslängen und Winkeln (\AA , $^\circ$): Mo-N(1) 2.2691(8), Mo-C(20) 1.9208(10), Mo-P(1) 2.3783(3), Mo-P(2) 2.3579(3), Mo-Cl(1) 2.4052(2), Mo-Cl(2) 2.4792(3); P(1)-Mo-P(2) 128.03(1), N(1)-Mo-P(1) 72.20(2), N(1)-Mo-P(2) 73.65(2), N(1)-Mo-Cl(1) 163.04(2), N(1)-Mo-Cl(2) 79.27(2), N(1)-Mo-C(20) 114.82(4), Cl(1)-Mo-Cl(2) 83.88(1), Cl(1)-Mo-C(20) 82.07(3), Cl(2)-Mo-C(20) 165.87(3).

Abbildung 9: ORTEP Diagramm von $[\text{Mo}(\text{PNP}^{\text{Me-}i\text{Pr}})(\text{CO})\text{Br}_2]$ (**6a**) mit Bindungslängen und Winkeln (\AA , $^\circ$): Mo-N(1) 2.2665(12), Mo-C(20) 1.9209(15), Mo-P(1) 2.3847(4), Mo-P(2) 2.3620(4), Mo-Br(1) 2.5494(2), Mo-Br(2) 2.6301(3); P(1)-Mo-P(2) 128.01(2), N(1)-Mo-P(1) 72.13(3), N(1)-Mo-P(2) 73.97(3), N(1)-Mo-Br(1) 163.60(3), N(1)-Mo-Br(2) 78.98(3), N(1)-Mo-C(20) 115.05(5), Br(1)-Mo-Br(2) 84.79(1), Br(1)-Mo-C(20) 81.26(4), Br(2)-Mo-C(20) 165.88(4).

Abbildung 10: ORTEP Diagramm von $[\text{Mo}(\text{PNP}^{\text{Me-}i\text{Pr}})(\text{CO})_2]$ (**6b**) mit Bindungslängen und Winkeln (\AA , $^\circ$): Mo-N(1) 2.275(2), Mo-C(20) 1.915(3), Mo-P(1) 2.3825(7), Mo-P(2) 2.3764(7), Mo-I(1) 2.7657(3), Mo-I(2) 2.8504(3); P(1)-Mo-P(2) 126.11(2), N(1)-Mo-P(1) 74.11(6), N(1)-Mo-P(2) 70.91(6), N(1)-Mo-I(1) 165.50(5), N(1)-Mo-I(2) 79.54(5), N(1)-Mo-C(20) 115.13(9), I(1)-Mo-I(2) 86.36(1), I(1)-Mo-C(20) 79.32(8), I(2)-Mo-C(20) 163.17(7).

Im IR Spektrum gibt es eine Bande bei 1816 (**6a**), 1824 (**6b**) und 1813 (**6c**). Zum Vergleich mit den siebenfachkoordinierten kationischen $18e^-$ Mo(II) Komplexen sind die Phosphorsignale ins Tieffeld verschoben 206.9 (**6a**), 202.2 (**6b**), 207.0 (**6c**).

Wenn **6c** und **6b** in CH_2Cl_2 in Anwesenheit von THF und Acetonitril mit einem Silbersalz umgesetzt werden, entstehen die kationischen oktaedrischen Komplexe $[\text{Mo}(\text{PNP}^{\text{Me-}i\text{Pr}})(\text{CO})(\text{THF})\text{Cl}]\text{SbF}_6$ (**6d**) und $[\text{Mo}(\text{PNP}^{\text{Me-}i\text{Pr}})(\text{CO})(\text{NCCH}_3)]\text{SbF}_6$ (**6e**) (Schema 17).

Schema 17: Herstellung von Komplex **6d** und **6e**

Im IR Spektrum haben sich CO Banden zum Vergleich **6c** und **6b** auf 1831cm^{-1} und 1840cm^{-1} verschoben. Diese Komplexe wurden mittels Einkristall Röntgendiffraktion und ^1H -, $^{13}\text{C}\{^1\text{H}\}$ -, $^{31}\text{P}\{^1\text{H}\}$ NMR, charakterisiert (Tabelle 3, Abbildung 11).

Abbildung 11: ORTEP Diagramm von $[\text{Mo}(\text{PNP}^{\text{Me}}\text{-}i\text{Pr})(\text{CO})(\text{THF})\text{Cl}]\text{SbF}_6$ (**6d**) mit Bindungslängen und Winkeln (\AA , $^\circ$): Mo-N(1) 2.260(2), Mo-C(20) 1.913(4), Mo-P(1) 2.3853(9), Mo-P(2) 2.3717(8), Mo-Cl(1) 2.3966(8), Mo-O(2) 2.312(3); P(1)-Mo-P(2) 125.66(4), N(1)-Mo-P(1) 73.80(6), N(1)-Mo-P(2) 71.82(6), N(1)-Mo-Cl(1) 162.97(9), N(1)-Mo-O(2) 80.18(9), N(1)-Mo-C(20) 113.20(14), Cl(1)-Mo-O(2) 83.09(7), Cl(1)-Mo-C(20) 83.79(13), O(2)-Mo-C(20) 165.21(13).

3.3. Synthese von $\text{M}(\text{PNP-R})(\text{CO})_3$ ($\text{M} = \text{Mo}, \text{W}$)

$\text{Mo}(\text{CO})_3(\text{PNP-R})$ ($\text{R} = \text{Ph}, i\text{Pr}$ und $t\text{Bu}$) wurden laut Literatur¹⁰ hergestellt. Weiters wurde $[\text{Mo}(\text{PNP-R})(\text{CO})_3\text{Br}]\text{Br}$ durch Reduktion mit Natrium-Amalgam hergestellt (Schema 18).

Schema 18: Herstellung der Komplexe M(PNP-R)(CO)₃ (**4b, e, f** und **g**)

Die Umsetzung erfolgte von [M(PNP-R)(CO)₃X]X mit 10 % NaHg (3 Äquivalent Na) in THF (Schema 18). Zum Vergleich mit der Literatur hat diese Methode bei den Wolfram-Komplexen große Vorteile. Die Ausbeuten liegen zwischen 70-80 % und die Reaktionszeiten sind wesentlich kürzer. Die Charakterisierung erfolgte mittels ¹H-, ¹³C{¹H}-, ³¹P{¹H} NMR und Einkristall Röntgenstrukturanalysen (Tabelle 3, Abbildung 12 und 13). Die Komplexe sind verzerrte Oktaeder mit dem PNP Ligand meridional zum Metall koordiniert. Die Winkel zwischen P₁-W-P₂ und trans-C_{CO}-W-C_{CO} sind 154.43(4) und 165.7(2)° (**4f**) und 151.42(1) und 156.46(9)° (**4g**). Die Winkel sind äußerst abhängig vom Substituent am Phosphoratom.

Abbildung 12: ORTEP Diagramm von W(PNP-*i*Pr)(CO)₃ (**4f**) mit Bindungslängen und Winkeln (Å, °): W-C(18) 2.015(6), W-C(19) 2.013(6), W-C(20) 1.933(5), W-N(1) 2.255(4), W-P(1) 2.4090(14), W-P(2) 2.4015(14); P(1)-W-P(2) 154.42(5), N(1)-W-P(1) 77.31(11), N(1)-W-P(2) 77.16(11), N(1)-W-C(18) 100.8(2), N(1)-W-C(19) 93.3(2), N(1)-W-C(20) 175.8(2), C(18)-W-C(19) 165.8(2).

Abbildung 13: ORTEP Diagramm von $W(\text{PNP-}t\text{Bu})(\text{CO})_3$ (**4g**) mit Bindungslängen und Winkeln (\AA , $^\circ$): W-C(22) 1.941(3), W-C(23) 1.997(2), W-C(24) 2.001(2), W-N(1) 2.277(2), W-P(1) 2.4583(5), W-P(2) 2.4656(5); P(1)-W-P(2) 151.42(2), N(1)-W-P(1) 76.52(4), N(1)-W-P(2) 76.00(4), N(1)-W-C(22) 169.53(8), N(1)-W-C(23) 113.16(8), N(1)-W-C(24) 90.27(7), C(23)-W-C(24) 156.46(9).

Im $^{13}\text{C}\{^1\text{H}\}$ NMR Spektrum gibt es zwei Triplets für die CO Gruppen mit der Intensität 1:2 im Bereich von 206-221 ppm und 196-210 ppm. Im $^{31}\text{P}\{^1\text{H}\}$ NMR Spektrum gibt es ein Singulett mit einer $^1J_{\text{WP}}$ Kopplungskonstante im Bereich von 315-329 Hz. Das W-P Signal ist ein Satellit über dem Hauptsignal wegen dem NMR aktiven ^{183}W ($I = \frac{1}{2}$) Kern. Im IR Spektrum gibt es drei Bande für die CO Gruppen im Bereich von 1966-1759 cm^{-1} .

Der Komplex **4d** wurde durch Umsetzung von $\text{Mo}(\text{CO})_3(\text{CH}_3\text{CN})_3$ ^{10,11} mit $\text{PNP}^{\text{Me-}i\text{Pr}}$ (**2d**) in Acetonitril hergestellt (Schema 19). Die Charakterisierung erfolgte mittels ^1H -, $^{13}\text{C}\{^1\text{H}\}$ -, $^{31}\text{P}\{^1\text{H}\}$ NMR, IR und Einkristall Röntgendiffraktion gemacht (Tabelle 3, Abbildung 14). Die $^{13}\text{C}\{^1\text{H}\}$ NMR und IR Spektren sind ähnlich wie **4b** aber die Verschiebung im $^{31}\text{P}\{^1\text{H}\}$ NMR ist zum Vergleich **4b** ins Tieffeld nach 171.0 ppm verschoben.

Schema 19: Herstellung der Komplex $\text{Mo}(\text{PNP}^{\text{Me-}i\text{Pr}})(\text{CO})_3$ (**4d**)

Abbildung 14: ORTEP Diagramm von $\text{Mo}(\text{PNP}^{\text{Me-}i\text{Pr}})(\text{CO})_3$ (**4d**) mit Bindungslängen und Winkeln (\AA , $^\circ$): Mo-C(14) 1.956(2), Mo-C(15) 2.0153(13), Mo-N(1) 2.2589(15), Mo-P(1) 2.3977(5), Mo-P(2) 2.4070(5); P(1)-Mo-P(2) 155.25(2), N(1)-Mo-P(1) 77.74(4), N(1)-Mo-P(2) 77.51(4), N(1)-Mo-C(15) 98.52(4).

3.4. Synthese von $[M(\text{PNP-R})(\text{CO})_3\text{H}]\text{BF}_4$ Komplexe**Schema 20:** Herstellung der Komplexe $[M(\text{PNP-R})(\text{CO})_3\text{H}]\text{BF}_4$ (**7a-d**, **8a-c**)

Diese Komplexe wurden durch Umsetzung von **4a-g** mit HBF_4 hergestellt (Schema 20). Die Komplexe sind siebenfach koordiniert und kationisch. Die PNP-R Liganden haben eine meridional Position zum Metallzentrum und sind dynamisch in Lösung. Es erfolgt eine Pseudorotation zwischen H und der Carbonylgruppe in der äquatorialen Position (Abbildung 15, 16, 17).

Abbildung 15: Energiediagramm (freie Energie in kcal/mol) für die "Pseudorotation" von CO und Hydrid in den Komplexen $[M(\text{PNP})(\text{CO})_3\text{H}]^+$ (M = W, Mo).

Abbildung 16: Optimierte Struktur (DFT/B3LYP) des Wolfram Komplexes $[W(\text{PNP-Ph})(\text{CO})_3\text{H}]^+$ (**8a**) (oben), Übergangszustand (unten). Phenyl - und Wasserstoffatome wurden der Übersichtlichkeit wegen weggelassen.

Abbildung 17: Optimierte Struktur (DFT/B3LYP) des Wolfram Komplexes $[W(\text{PNP-}t\text{Bu})(\text{CO})_3\text{H}]^+$ (**8c**) (oben), Übergangszustand (unten). $t\text{Bu}$ - und Wasserstoffatome wurden der Übersichtlichkeit wegen weggelassen.

Diese Rotation ist bei Molybdän Komplexen schneller als bei Wolfram Komplexen und hängt von der Alkylgruppe am Phosphor ab (Abbildung 11). Wegen dieser Rotation findet man kein Signal bei Raumtemperatur im ^{31}P NMR und im ^1H NMR sieht man nur ein Triplett für die Hydrid Liganden. Bei den tiefen Temperaturen (-60°C) gibt es ein dublettisches Dublett sowohl im ^{31}P NMR als auch im ^1H NMR (Abbildung 18, Tabelle 3).

Abbildung 18: Das temperaturabhängige 300 MHz ^1H NMR Spektrum von $[\text{Mo}(\text{PNP-Ph})(\text{CO})_3\text{H}]\text{BF}_4$ (7a) in CD_2Cl_2 (Hydridregion)

Außer ^1H , $^{13}\text{C}\{^1\text{H}\}$, $^{31}\text{P}\{^1\text{H}\}$ NMR und IR wurden die Komplexe mit Einkristall Röntgendiffraktion charakterisiert (Abbildung 19, 20, 21).

Abbildung 19: ORTEP Diagramm von $[\text{Mo}(\text{PNP-Ph})(\text{CO})_3\text{H}]\text{BF}_4$ (**7a**) mit Bindungslängen und Winkeln (\AA , $^\circ$): Mo-H(1) 1.67(4), Mo-C(30) 2.0368(15), Mo-C(31) 2.0465(15), Mo-C(32) 2.017(3), Mo-N(1) 2.2357(11), Mo-P(1) 2.4409(4), Mo-P(2) 2.4489(4); P(1)-Mo-P(2) 154.64(1), N(1)-Mo-P(1) 77.39(3), N(1)-Mo-P(2) 77.39(3), N(1)-Mo-C(30) 87.62(5), N(1)-Mo-C(31) 86.97(5), N(1)-Mo-C(32) 163.73(9), N(1)-Mo-H(1) 146.0(15), C(32)-Mo-H(1) 50.2(15).

3.5 Synthese von Mo(III) und Mo(IV) PNP-R Halokomplexe

Schema 21: Herstellung der Mo(III) und Mo(IV) Komplexe (**10a**, **b**)

Die Komplexe wurden durch Umsetzung von $\text{Mo}(\text{PNP-R})(\text{CO})_3$ ($\text{R} = \text{Ph}, i\text{Pr}$) mit Br_2 in Toluol hergestellt (Schema 21). Bei der Umsetzung von $\text{Mo}(\text{PNP-Ph})(\text{CO})_3$ entstand $\text{Mo}(\text{PNP}^{2\text{Br}}\text{-Ph})\text{Br}_4$ mit Ringsubstitution in den 3 und 5 Positionen (Abbildung 22). Der Komplex ist siebenfach koordiniert und hat eine verzerrte Oktaederstruktur. Zwei Bromatome liegen horizontal zur PNP Ebene, die andere Bromatome liegen in der PNP Ebene.

Mit dem größeren $i\text{Pr}$ Rest entsteht ein sechsfachkoordinierter oktaedrischer Komplex mit der formalen Oxidationstufe +III. Zwei Bromatome liegen wie bei **10a** horizontal zur PNP-Ebene und drittes Bromatom liegt in der PNP-Ebene trans zum Stickstoffatom (Abbildung 23). Zum Vergleich zu **10a** ist **10b** hat keine verzerrte Struktur sondern ist ein fast perfekter Oktaeder. Die Winkeln zwischen N1-Mo1-Br sind 142.89° (**10a**) und 178.79° (**10b**).

Abbildung 22: ORTEP Diagramm von $[\text{Mo}(\text{PNP}^{2\text{Br}}\text{-Ph})\text{Br}_4]$ (**10a**) mit Bindungslängen und Winkeln (\AA , $^\circ$): Mo-N(1) 2.298(2), Mo-P(1) 2.5284(5), Mo-P(2) 2.5248(6), Mo-Br(1) 2.6122(3), Mo-Br(2) 2.5956(3), Mo-Br(3) 2.5438(3), Mo-Br(4) 2.5310(3); P(1)-Mo-P(2) 148.15(2), N(1)-Mo-P(1) 73.99(4), N(1)-Mo-P(2) 74.58(4), N(1)-Mo-Br(1) 142.89(4), N(1)-Mo-Br(2) 139.86(4), N(1)-Mo-Br(3) 86.70(4), N(1)-Mo-Br(4) 85.17(4), P(1)-Mo1-N(1)-C(1) $-14.60(12)$.

Abbildung 23: ORTEP Diagramm von $[\text{Mo}(\text{PNP-}i\text{Pr})\text{Br}_3]$ (**10b**) mit Bindungslängen und Winkeln (\AA , $^\circ$): Mo-N(1) 2.209(2), Mo-P(1) 2.5221(7), Mo-P(2) 2.5170(7), Mo-Br(1) 2.5256(3), Mo-Br(2) 2.5405(3), Mo-Br(3) 2.5806(3); P(1)-Mo-P(2) 156.20(2), N(1)-Mo-P(1) 78.39(6), N(1)-Mo-P(2) 78.26(6), N(1)-Mo-Br(1) 178.79(6), N(1)-Mo-Br(2) 88.71(5), N(1)-Mo-Br(3) 87.95(5), P(1)-Mo1-N(1)-C(1) 179.56(19).

Die Komplexe sind paramagnetisch und konnten nicht mittels NMR Spektroskopie charakterisiert werden. Die Charakterisierung erfolgte mittels Einkristall Röntgendiffraktion und Massenspektroskopie.

3.6 Synthese von $[\text{Mo}(\text{PNP-R})(\text{O})\text{X}]\text{X}$ -Komplexen

Schema 22: Herstellung des Komplexes $[\text{Mo}(\text{PNP-}i\text{Bu})(\text{O})\text{Br}]\text{Br}$ (**9a**)

Der Komplex **9a** wurde durch Umsetzung von $\text{Mo}(\text{PNP-}t\text{Bu})(\text{CO})_3$ mit Br_2 in Anwesenheit von Luft hergestellt (Schema 22). Wegen der schwer zu kontrollierenden Stöchiometrie des Sauerstoffes entstanden einige Nebenprodukte, die nicht identifiziert werden konnten.

Schema 23: Herstellung des Komplexes $[\text{Mo}(\text{PNP}^{\text{Me}}-t\text{Pr})(\text{O})\text{I}]\text{SbF}_6$ (**9b**)

Der Komplex **9b** wurde durch Umsetzung von **6b** mit dem Silbersalz AgSbF_6 in Anwesenheit von Luft hergestellt (Schema23). Beide Mono-oxo-Komplexe wurden mittels ^1H , $^{31}\text{P}\{^1\text{H}\}$ NMR, und ein Einkristall Röntgendiffraktion charakterisiert (Tabella 3). Die Mono-oxo-Komplexe besitzen eine verzerrte quadratisch-pyramidale Struktur. Der Oxoligand steht senkrecht zur PNP-Ebene und besitzt eine Metall-O dreifache Bindung.

Tabelle 3. IR, ^1H , $^{31}\text{P}\{^1\text{H}\}$ NMR, und $^{13}\text{C}\{^1\text{H}\}$ NMR Daten der Molybdän und Wolfram Komplexe mit PNP Liganden.

Allgemeines

Alle Experimente wurden unter Inertgas (Argon) in einer Glovebox und mit Hilfe der Schlenktechnik durchgeführt. Verwendete Reagenzien wurde ohne weiter Reinigung eingesetzt. Die Lösungsmittel wurden nach Standardvorschriften gereinigt und getrocknet.³¹ Deuterierte Lösungsmittel wurden bei Aldrich gekauft und über getrocknetes 4 Å Molekularsieb aufbewahrt. Die Komplexe (FeCp(CO)₂Br, FeCp(CO)₂Cl³² und Fe(CO)₄Br₂³³) wurden nach Literaturvorschriften hergestellt. Die Liganden (PNP-Ph, PNP-*i*Pr und PNP-*t*Bu) und die Komplexe (Mo(PNP-Ph), Mo(PNP-*i*Pr) und Mo(PNP-*t*Bu)) wurden nach Literaturvorschriften hergestellt.²⁴ ¹H, ¹³C und ³¹P{¹H} NMR Spektren wurde mit einem Bruker AVANCE-250 Spektrometer aufgenommen und gegen SiMe₄ und H₃PO₄ (85%) referenziert. FT-IR Spektren wurden an Bruker Tensor 27 Spektrometer aufgenommen.

1. PN- Liganden

Ph₂PNiPr (1a)

In einem Dreihalskolben mit Rückflußkühler wurde Isopropylamin (3.3 g, 0.055 mol) in Et_2O (150 mL) vorgelegt. Dann wurde Chlorodiphenylphosphin (5.97 g, 0.027 mol) unter Eiskühlung zugetropft. Danach wurde die Eiskühlung entfernt und das Reaktionsgemisch über Nacht gekocht. Anschließend das Reaktionsgemisch wurde unter Argon filtriert und das Lösungsmittel am Hochvakuum abgezogen.

Ausbeute: 6.0 g (91 %) weiß kristallin

Chemical Formula: $\text{C}_{15}\text{H}_{18}\text{NP}$

Elementar Analyse: $\text{C}_{15}\text{H}_{18}\text{NP}$ (M.G: 243.12): C, 7.05; H, 7.46; N, 5.76; P, 12.73

³¹P{¹H}-NMR (δ, CDCl₃, 20 °C): 69.9

2. PNP- Liganden

N,N'-bis(diisopropylphosphino-boran)-2,6-diaminopyridin (PNP-*i*Pr) (2b·BH₃).

PNP-*i*Pr (7.00 g, 20.50 mmol) wurde in THF (100mL) gelöst. Dann wurde BH₃·THF (1.0 M, 43.1 mL, 43.06 mmol) langsam dazugegeben. Das Reaktionsgemisch wurde 30 min bei Raumtemperatur gerührt. Anschließend wurde das Lösungsmittel am Hochvakuum abgezogen und getrocknet.

Ausbeute: 7.57 g (100 %) weißes Pulver.

Elementar Analyse: C₁₇H₃₉B₂N₃P₂ (M.G: 369.08): C, 55.32; H, 10.65; B, 5.86; N, 11.39; P, 16.78

¹H-NMR (δ, CDCl₃, 20 °C): 7.32 (t, *J* = 7.9 Hz, 1H, py⁴), 6.26 (d, *J* = 7.9, 2H, py^{3,5}), 4.58 (d, *J* = 8.4 Hz, 2H, NH), 2.62 (septd, *J*₁ = 6.9 Hz, *J*₂ = 13.7 Hz, 4H, CH(CH₃)₂), 1.16 (m, 24H, CH(CH₃)₂), 0.60 - -0.15 (bs, 6H, BH₃).

¹³C{¹H}-NMR (δ, CDCl₃, 20 °C): 154.4 (s, py^{2,6}), 140.1 (s, py⁴), 103.1 (s, py^{3,5}), 24.5 (d, *J* = 36.3 Hz, CH(CH₃)₂), 17.2 (d, *J* = 4.3 Hz, CH(CH₃)₂), 17.0 (s, CH(CH₃)₂).

³¹P{¹H}-NMR (δ, CDCl₃, 20 °C): 88.5 (br, m).

N,N'-bis(diisopropylphosphino-boran)-N,N'-methyl-2,6-diaminopyridin (PNP^{Me}-iPr) (2d·BH₃).

2d·BH₃ (7.45 g, 20.19 mmol) wurde in THF (50 mL) gelöst und auf -20°C gekühlt. Danach wurde *n*-BuLi (17.0 mL, 2.5 M, 41.39 mmol) langsam zugetropft. Das Reaktionsgemisch wurde bei der Raumtemperatur 2 h gerührt. Danach wurde Methyljodid (3.15 mL, 50.46 mmol) langsam mit der Spritze zugetropft. Nach dem Rühren (12 h) bei der Raumtemperatur wurde die Reaktion mit einer gesättigten Ammoniumchloridlösung (100 mL) und konzentriertem Ammoniak gequenchet. Die wässrige Phase wurde mit CH₂Cl₂ zweimal extrahiert und die gesammelte organische Phase wurde mit Brain gewaschen und mit Natriumsulfat getrocknet. Nach dem Abziehen des Lösungsmittel am Rotavapor wurde das Produkt durch Kieselgel mit THF gereinigt.

Ausbeute: 5.05 g (63 %) weißes Pulver.

Elementar Analyse: C₁₉H₄₃B₂N₃P₂ (M.G: 397.13): C, 57.46; H, 10.91; B, 5.44; N, 10.58; P, 15.60

¹H-NMR (δ, CDCl₃, 20 °C): 7.48 (t, *J* = 8.0 Hz, 1H, py⁴), 6.49 (d, *J* = 8.0, 2H, py^{3,5}), 3.17 (d, *J* = 7.9 Hz, 6H, NCH₃), 2.80 (septd, *J* = 7.0 Hz, *J* = 21.2 Hz, 4H, CH(CH₃)₂), 1.22 (dd, *J*₁ = 6.9 Hz, *J*₂ = 16.5 Hz, 12H, CH(CH₃)₂), 1.03 (dd, *J* = 7.0 Hz, *J* = 15.11 Hz, 12H, CH(CH₃)₂), 0.70 - -0.30 (bs, 6H, BH₃).

¹³C{¹H}-NMR (δ, CDCl₃, 20 °C): 156.9 (s, py^{2,6}), 139.1 (s, py⁴), 105.8 (s, py^{3,5}), 37.6 (s, NCH₃), 25.6 (d, *J* = 36.2 Hz, CH(CH₃)₂), 17.8 (s, CH(CH₃)₂), 17.2 (s, CH(CH₃)₂).

³¹P{¹H}-NMR (δ, CDCl₃, 20 °C): 105.9 (br, m).

N,N'-bis(diisopropylphosphino)-N,N'-methyl-2,6-diaminopyridin (PNP^{Me}-iPr) (2d).

2d·BH₃ (5.00 g, 12.59 mmol) wurde in 100 mL Et₂NH 72 h refluxiert. Das Lösungsmittel wurde am Rotavapor einrotiert. Der Rückstand wurde in THF gelöst, über Celite filtriert. Die erhaltene gelbliche Flüssigkeit wurde aus Acetonitril umkristallisiert.

Ausbeute: 3.25 g (70 %) weißes Pulver.

Elementar Analyse: C₁₉H₃₇N₃P₂ (M.G: 369.46): C, 61.77; H, 10.09; N, 11.37; P, 16.77

¹H-NMR (δ, CD₂Cl₂, 20 °C): 7.22 (t, *J* = 8.0 Hz, 1H, py⁴), 6.64 (bs, py^{3,5}), 3.04 (d, *J* = 2.3 Hz, 6H, NCH₃), 2.22 (bs, 4H, CH(CH₃)₂), 1.10 (dd, *J* = 6.9 Hz, *J* = 16.9 Hz, 12H, CH(CH₃)₂), 0.98 (dd, *J* = 7.0 Hz, *J* = 12.1 Hz, 12H, CH(CH₃)₂).

$^{13}\text{C}\{^1\text{H}\}$ -NMR (δ , CD_2Cl_2 , 20°C): 160.4 (s, $\text{py}^{2,6}$), 136.9 (s, py^4), 99.1 (d, $J = 22.3$ Hz, $\text{py}^{3,5}$), 33.7 (bs, NCH_3), 26.2 (d, $J = 15.3$ Hz, $\text{CH}(\text{CH}_3)_2$), 19.4 (s, $\text{CH}(\text{CH}_3)_2$), 19.2 (s, $\text{CH}(\text{CH}_3)_2$), 19.0 (s, $\text{CH}(\text{CH}_3)_2$).

$^{31}\text{P}\{^1\text{H}\}$ -NMR (δ , CD_2Cl_2 , 20°C): 81.3 (bs).

3. Eisen - Komplexe

$\text{Fe}(\text{Ph}_2\text{PNiPr})_2(\text{CO})_2\text{Br}_2$ (3a)

Eisen(II)tetracarbonyldibromid (1 g, 3.05 mmol) wurde im Schlenkrohr in Methylenchlorid (10 mL) gelöst. Danach wurde in Methylenchlorid gelöste Ph_2PNiPr (1.52 g, 6.25 mmol) unter Kühlung zugetropft. Nach dem Rühren Übernacht wurde das Reaktionsgemisch über Celite, Seesand und Glaswolle filtriert und das Lösungsmittel am Hochvakuum abgezogen. Anschließend wurde das Produkt mit Diethylether gewaschen und getrocknet.

Ausbeute: 1.96 g (85 %) gelbes Pulver

Elementar Analyse: $\text{C}_{32}\text{H}_{36}\text{Br}_2\text{FeN}_2\text{O}_2\text{P}_2$ (M.G: 758.24): C, 50.69; H, 4.79; Br, 21.08; Fe, 7.37; N, 3.69; O, 4.22; P, 8.17

$^{13}\text{C}\{^1\text{H}\}$ NMR (δ , CD_2Cl_2 , 20 °C): 205.5 (t, $J = 8.5$ Hz, CO), 198.0 (t, $J = 8.1$ Hz, CO), 160.1 (d, $J = 3.9$ Hz, py), 141.6 (s, py), 100.4 (d, $J = 6.4$ Hz, py), 31.9 (d, $J = 25.5$ Hz, $\text{CH}(\text{CH}_3)_2$), 18.0 (d, $J = 4.2$ Hz, $\text{CH}(\text{CH}_3)_2$).

$^{31}\text{P}\{^1\text{H}\}$ NMR (δ , CD_2Cl_2 , 20 °C): 125.9 (d, $^2J_{\text{PP}} = 80.0$ Hz), 108.6 (d, $^2J_{\text{PP}} = 80.0$ Hz).

IR (ATR, 25 °C): 2027 (ν_{CO}), 1910 (ν_{CO}), 1906 (ν_{CO}).

[W(PNP-*t*Bu)(CO)₃H]BF₄ (8g).

Die Reaktion wurde analog zu **8a** mit W(PNP-*t*Bu)(CO)₃ (200 mg, 0.30 mmol) und HBF₄ (18 μL, 0.45 mmol, 54% Lösung in Et₂O) durchgeführt.

Ausbeute: 207 mg (90%) hell gelbes Pulver

Elementar Analyse: C₂₄H₄₂BF₄N₃O₃P₂W (M.G: 753,20): C, 38.27; H, 5.62; B, 1.44; F, 10.09; N, 5.58; O, 6.37; P, 8.22; W, 24.41

¹H NMR (δ, Aceton-d₆, 20 °C): 8.00 (bs, 2H, NH), 7.60 (t, *J* = 6.7 Hz, 1H, py), 6.75 (d, *J* = 8.3 Hz, 2H, py), 1.59 (s, 18H, C(CH₃)₃), 1.53 (s, 18H, C(CH₃)₃). -4.16 (dd, ²*J*_{HP} = 37.8 Hz, ²*J*_{HP} = 50.8 Hz, 1H, WH).

³¹P{¹H} NMR (δ, CD₂Cl₂, 20 °C): 141.1 (d, ²*J*_{PP} = 83.6 Hz), 126.8 (d, ²*J*_{PP} = 83.6 Hz).

IR (ATR, 25 °C): 2021 (ν_{CO}), 1934 (ν_{CO}), 1897 (ν_{CO}).

9-Mo(III) und Mo(IV) Komplexe**Mo(PNP^{2Br}-Ph)Br₄ (10a)**

Mo(PNP-Ph)(CO)₃ (2.9 g, 4.41 mmol) wurde mit Br₂ (0.700 mL, 13.5 mmol) in Toluol (20 mL) bei 0°C umgesetzt. Nach 4 h wurde das Lösungsmittel abdekantiert und das Produkt mit Et₂O gewaschen danach unter Hochvakuum getrocknet.

Ausbeute: 4.17 g (90%) oranges Pulver

Elementar Analyse: C₂₉H₂₃Br₆MoN₃P₂ (M.G: 1050,84): C, 33.15; H, 2.21; Br, 45.62; Mo, 9.13; N, 4.00; P, 5.90

Mo(PNP-*i*Pr)Br₃ (10b)

Die Reaktion wurde analog zu 9a mit Mo(PNP-*i*Pr)(CO)₃ (720 mg, 1.38 mmol) und Br₂ (217 µL, 4.14 mmol) durchgeführt.

Ausbeute: 880 mg (94%) oranges Pulver

Elementar Analyse: C₁₇H₃₃Br₃MoN₃P₂ (M.G: 677,08): C, 30.16; H, 4.91; Br, 35.40; Mo, 14.17; N, 6.21; P, 9.15

10-Molybdänoxokomplexe

 $[\text{Mo}(\text{PNP-}t\text{Bu})(\text{O})\text{Br}]\text{Br}$ (9a)

$\text{Mo}(\text{PNP-}t\text{Bu})(\text{CO})_3$ (200 mg, 0.35 mmol) wurde mit Br_2 (19 μL , 0.37 mmol) in CH_2Cl_2 umgesetzt. Nach dem Rühren Übernacht wurde das Gemisch über Glaswolle und Celite filtriert danach wurde das Lösungsmittel am Hochvakuum abgezogen. Nachdem das Produkt mit Et_2O gewaschen hat wurde es getrocknet.

Ausbeute: 117 mg (50%) hell grünes Pulver

Elementar Analyse: $\text{C}_{21}\text{H}_{41}\text{Br}_2\text{MoN}_3\text{OP}_2$ (M.G: 669,29): C, 37.69; H, 6.17; Br, 23.88; Mo, 14.34; N, 6.28; O, 2.39; P, 9.26

^1H NMR (δ , CD_2Cl_2 , 20 °C): 9.58 (bs, 2H, NH), 7.63 (d, $J = 8.8$ Hz, 2H, py), 6.37 (t, $J = 7.5$ Hz, 1H, py), 1.66 (m, 18H, $\text{C}(\text{CH}_3)_3$), 1.34 (m, 18H, $\text{C}(\text{CH}_3)_3$).

$^{31}\text{P}\{^1\text{H}\}$ NMR (δ , CD_2Cl_2 , 20 °C): 147.2

 $[\text{Mo}(\text{PNP}^{\text{Me-}i\text{Pr}})(\text{O})\text{I}]\text{SbF}_6$ (9b)

$\text{Mo}(\text{PNP}^{\text{Me-}i\text{Pr}})(\text{CO})(\text{I})_2$ (200 mg, 0.27 mmol) wurde mit AgSbF_6 (97 mg, 0.28 mmol) in CH_2Cl_2 :in Anwesenheit von Luft umgesetzt. Die Reaktion wurde Übernacht gerührt danach wurde über Glaswolle und Celite filtriert. Das Lösungsmittel wurde am Hochvakuum abgezogen und das Produkt wurde getrocknet.

Ausbeute: 210 mg (92%) grünes Pulver

Elementar Analyse: $C_{19}H_{37}F_6IMoN_3OP_2Sb$ (M.G: 844,08): C, 27.04; H, 4.42; F, 13.50; I, 15.03; Mo, 11.37; N, 4.98; O, 1.90; P, 7.34; Sb, 14.43

1H NMR (δ , CD_2Cl_2 , 20 °C): 8.05 (t, $J = 8.38$ Hz, 1H, py), 6.64 (d, $J = 8.49$ Hz, 2H, py), 3.33 (s, 6H, NCH_3), 3.06 (m, 2H, $CH(CH_3)_2$), 2.98 (m, 2H, $CH(CH_3)_2$), 1.30 (m, 18H, $CH(CH_3)_2$), 0.76 (m, 6H, $CH(CH_3)_2$).

$^{13}C\{^1H\}$ NMR (δ , CD_2Cl_2 , 20 °C): 218.5 (t, $J = 6.35$ Hz, CO), 162.3 (t, $J = 6.79$ Hz, py), 146.0 (s, py), 128.9 (s, py), 74.4 (s, thf), 36.3 (s, $N(CH_3)_2$), 31.0 (t, $J = 12.45$ Hz, $CH(CH_3)_2$), 25.5 (s, thf), 19.5 (s, $CH(CH_3)_2$), 19.2 (s, $CH(CH_3)_2$), 19.0 (s, $CH(CH_3)_2$), 18.8 (s, $CH(CH_3)_2$).

$^{31}P\{^1H\}$ NMR (δ , CD_2Cl_2 , 20 °C): 161.0

DFT-Rechnungen und Strukturbestimmung

Theoretische Berechnungen

Alle Berechnungen wurde mit dem Gaussian 09 Software Paket auf Phoenix Linux Cluster der TU Wien durchgeführt.³⁴ Die Geometrien und Energien der Modelkomplexe und deren Übergangszustände wurden mit dem B3LYP Funktional optimiert.³⁵ Für die Beschreibung der Elektronen der Eisen, Molybdän und Wolframatome wurde das Stuttgart/Dresden ECP (SDD) verwendet,³⁶ für alle anderen Atome wurde der 6-31g** Basissatz verwendet.³⁷

Kristallographische Strukturbestimmung

Kristallographische Daten und experimentelle Details finden sich in den Tabellen 4-5. Alle röntgenographischen Daten wurden bei $T = 100$ K auf einem Bruker Kappa Apex-2 CCD Flächendetektor-Diffraktometer (Mo- $K\alpha$ Strahlung, Graphitmonochromator ($\lambda = 0.71073$ Å), φ - und ω - Scan Frames im Ausmaß von Vollkugeln des reziproken Raums) gesammelt. Korrekturen wurden für Absorption und $\lambda/2$ -Effekt wurden mit dem Programm SADABS vorgenommen.³⁸ Die Kristallstrukturen wurden unter Verwendung des Programms SHELXS97³⁹ gelöst. Strukturverfeinerungen erfolgten auf Basis von F^2 -Werten mit dem Programm SHELXL97. Nicht-Wasserstoffatome wurden anisotrop verfeinert, Wasserstoffatome wurden in kritischen Fällen unrestringiert verfeinert. In allen anderen Fällen wurden sie in idealisierte Positionen eingesetzt und reitend verfeinert.

ABSTRACT

Treatment of $[\text{FeCp}(\text{CO})_2\text{Cl}]$ with 1 equiv of the amidophosphine ligands $\text{Li}[\text{R}_2\text{PNR}']$ ($\text{R} = \text{Ph}, i\text{Pr}, \text{R}' = i\text{Pr}, t\text{Bu}, \text{Cy}$) afforded complexes of the type $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-\text{C}=\text{O})-\text{NiPr}-\text{PPh}_2]$ (**1a**), $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-\text{C}=\text{O})-\text{NtBu}-\text{PPh}_2]$ (**1b**), and $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-\text{C}=\text{O})-\text{NCy}-\text{PiPr}_2]$ (**1c**) in 40–50% yields. Complex **1a** was also formed when $[\text{FeCp}(\text{CO})_2(\text{PPh}_2\text{NH}i\text{Pr})]^+$ (**2**) was reacted with 1 equiv of KOtBu . These complexes feature a four-membered carboxamido-phospha-ferracycle as a result of an intramolecular nucleophilic attack of the amidophosphine ligand on coordinated CO. Upon treatment of **1a** with the electrophile $[\text{Me}_3\text{O}]\text{BF}_4$ the aminocarbene complex $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})=\text{C}(\text{OMe})-\text{NiPr}-\text{PPh}_2)]^+$ (**3**) was obtained bearing an aza-phospha-carbene moiety. Upon treatment of *cis,trans,cis*- $[\text{Fe}(\text{CO})_2(\text{Ph}_2\text{PNH}i\text{Pr})_2(\text{Br})_2]$ (**4a**) and *cis,trans,cis*- $[\text{Fe}(\text{CO})_2(\text{Ph}_2\text{PNH}t\text{Bu})_2(\text{Br})_2]$ (**4b**) with KOtBu the carboxamido-phospha-ferracycles *trans*- $[\text{Fe}(\text{CO})_2(\kappa^2(\text{C},\text{P})-\text{C}=\text{O})-\text{NiPr}-\text{PPh}_2](\text{Ph}_2\text{PNH}i\text{Pr})\text{Br}$ (**5a**) and *trans*- $[\text{Fe}(\text{CO})_2(\kappa^2(\text{C},\text{P})-\text{C}=\text{O})-\text{NtBu}-\text{PPh}_2](\text{Ph}_2\text{PNH}t\text{Bu})\text{Br}$ (**5b**) were formed in moderate yield. Finally, representative structures were determined by X-ray crystallography.

1. Introduction

Aminophosphines of the type $\text{PR}_2\text{NHR}'$ containing a direct polar $\text{P}(\text{III})-\text{N}$ bonds have received considerable attention in recent years as versatile ligands for transition metals [1]. They are accessible in large quantities through the use of relatively simple condensation processes from inexpensive starting materials, i.e., primary amines and PR_2Cl compounds which contain dialkyl or diaryl substituents as well as achiral and chiral $\text{P}-\text{O}$ and $\text{P}-\text{N}$ containing phosphine units. Thus, variations of electronic, steric, and stereochemical parameters may be achieved in a very facile fashion. Due to their soft/hard donor atoms as well their acidic NH hydrogen, these polyfunctional ligands exhibit numerous coordination modes as illustrated in Scheme 1. As middle and late transition metals **M** are concerned $\text{PR}_2\text{NHR}'$ ligands typically coordinate in $\kappa^1(\text{P})$ -fashion **I** [2], while $\kappa^1(\text{N})$ -coordination is unknown. Upon deprotonation of the $\text{PR}_2\text{NHR}'$ ligands, anionic amidophosphines $[\text{PR}_2\text{NR}']^-$ are readily obtained which exhibit a higher affinity toward electropositive metals due to their increased nucleophilicity at the N-site. Thus, in conjunction with early transition metals **M'**, amidophosphine ligands were shown to display $\kappa^2(\text{P},\text{N})$ coordination **II**, and,

albeit less common, also $\kappa^1(\text{N})$ -coordination **III**, while in the presence of both early and middle/late transition metals, amidophosphine ligands were shown to act as μ^2 bridging ligand thereby forming heterobimetallic complexes of the type **IV** [3,4].

Besides interesting structural features, $\text{PR}_2\text{NHR}'$ ligands display various reactivities opening up a range of synthetically useful transformations [5]. For instance, we have recently shown [6] that in vinylidene and allenylidene complexes $[\text{RuCp}(\text{PPh}_2\text{NHR}')_2(=\text{C}=\text{C})_n=\text{CHR}')]^+$ and $[\text{RuTp}(\text{PPh}_2\text{NHR}')_2(=\text{C}=\text{C})_n=\text{CHR}')]^+$ ($n = 0, 1$; $\text{R} = \text{Ph}, n\text{-Pr}$; $\text{R}' = \text{alkyl}, \text{aryl}$; $\text{Tp} = \text{trispyrazoloylborate}$) an intramolecular addition of the NHR' moiety to the α -carbon of the cumulene moiety takes place (Scheme 2) resulting in the formation of novel four-membered aza-phospha-carbenes (Scheme 3, A). Complexes of the types $[\text{RuCp}(\text{PPh}_2\text{NHPh})(\text{CH}_3\text{CN})_2]^+$ and $[\text{RuCp}^*(\text{PR}_2\text{NHR}')(\text{CH}_3\text{CN})_2]^+$ ($\text{R} = \text{Ph}, i\text{-Pr}, \text{R}' = \text{Ph}, \text{C}_6\text{F}_5$) have been found to react with terminal alkynes and diynes to give amido butadiene complexes involving $\text{PR}_2\text{NHR}'$ ligand migration (Scheme 3, B) [7,8]. Bunten et al. reported [9] the synthesis of the dinuclear ruthenium complex $[\text{Ru}_2(\text{CO})_3(\mu^2\text{-PPh}_2)(\mu^2\text{-Ph}_2\text{PNMePPh}_2)(\kappa^2(\text{C},\text{P})-\text{C}=\text{O})\text{NMePPh}_2]$ containing a carboxamido-phospha-ruthenacyclic moiety (Scheme 3, C). Herberhold et al. reported on the preparation of half sandwich complexes of the type $[\text{MCp}(\text{CO})_2\text{C}(\text{C}=\text{O})\text{N}(\text{S-NHPtBu}_2)\text{PtBu}_2]$ ($\text{M} = \text{Cr}, \text{Mo}, \text{W}$) by reacting $[\text{MCp}(\text{CO})_3\text{H}]$ with $\text{PtBu}_2\text{PN} = \text{S}=\text{NPtBu}_2$

Scheme 1. Most common bonding modes of aminophosphine and amidophosphine ligands.

(Scheme 3, D) [10]. As iron complexes are concerned, $[\text{FeCp}(\text{CO})_2(\text{PPh}_2\text{NHNMe}_2)]^+$ bearing a hydrazinophosphine ligand, which is closely related to $\text{PR}_2\text{NHR}'$ ligands, was shown to react with $n\text{BuLi}$ to give the carboxamido-phospha-ferracycle $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NNMe}_2-\text{PPh}_2)]$ (Scheme 3, E) [11].

In the present paper we report on the synthesis of iron(II) complexes containing aminophosphine ligands of the type $\text{PR}_2\text{NHR}'$ with $\text{R} = \text{Ph}$, $i\text{Pr}$, $\text{R}' = i\text{Pr}$, $t\text{Bu}$, Cy . We describe the reactivity of these complexes yielding, upon treatment with strong bases, novel cyclic four-membered carboxamido-phospha-ferracycle formed via intramolecular addition of the amine moiety of the bifunctional aminophosphine ligand according to Scheme 4.

2. Results and discussion

Treatment of $[\text{FeCp}(\text{CO})_2\text{Cl}]$ with 1 equiv of the amidophosphine ligands $[\text{R}_2\text{PNR}']^-$ ($\text{R} = \text{Ph}$, $i\text{Pr}$, $\text{R}' = i\text{Pr}$, $t\text{Bu}$, Cy), prepared *in situ* by the reaction of $\text{R}_2\text{PNHR}'$ with $n\text{BuLi}$ in THF at -20°C , afforded complexes of the type $[\text{FeCp}(\text{CO})(\kappa^2[\text{C},\text{P}](\text{C}=\text{O})-\text{NiPr}-\text{PPh}_2)]$ (**1a**), $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{N}t\text{Bu}-\text{PPh}_2)]$ (**1b**), and $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NCy}-\text{PiPr}_2)]$ (**1c**) in reasonable isolated yields (40–50%) (Scheme 5). Although no intermediate could be detected spectroscopically, it is most likely that the deprotonated $\text{R}_2\text{PNHR}'$ ligand first forms a complex with a $\kappa^1(\text{P})$ -bound rather than a $\kappa^1(\text{N})$ -bound amidophosphine. It has to be noted that $\kappa^1(\text{N})$ coordinated $[\text{PR}_2\text{NR}']^-$ ligands to late transition metals are, according to our knowledge, unknown.

Subsequently, intramolecular, chelate assisted, nucleophilic attack of the amido moiety of the $\text{PR}_2\text{NR}'$ ligand at one of the two CO ligands took place resulting in the formation of novel four-membered carboxamido-phospha-ferracycle. This is also supported by the fact that **1a** is readily formed if the cationic dicarbonyl complex $[\text{FeCp}(\text{CO})_2(\text{PPh}_2\text{NHiPr})]^+$ with either Br^- (**2**) or BF_4^- (**2'**) as counterions was treated with $\text{KO}t\text{Bu}$ as base according to Scheme 6. In the absence of base, even at elevated temperatures, no reaction took place. Complexes **2** and **2'** were readily obtained by the treatment of $[\text{FeCp}(\text{CO})_2\text{Br}]$ with 1 equiv of the PPh_2NHiPr ligand in the absence or presence of NaBF_4 , respectively, in THF at room temperature (Scheme 6).

All complexes are thermally robust orange solids that are air stable both in the solid state and in solution for several days. Their identity was unequivocally established by ^1H , $^{13}\text{C}\{^1\text{H}\}$ and $^{31}\text{P}\{^1\text{H}\}$ NMR, IR spectroscopy, and elemental analysis. In addition, the

Scheme 2. Intramolecular addition of the NHR' moiety of an aminophosphine to the α -carbon of a cumulene moiety.

molecular structures of complexes **1a** and **2** were determined by X-ray crystallography. Structural views are depicted in Figs. 1 and 2 with selected bond distances and angles reported in the captions.

Complexes **1a–c** display a single resonance in the $^{31}\text{P}\{^1\text{H}\}$ NMR at 111.6, 113.0, and 140.0 ppm, respectively. In the $^{13}\text{C}\{^1\text{H}\}$ NMR spectra, the Cp ring gives rise to a singlet in the range of about 80–82 ppm. The CO ligands exhibit a low-field doublet at 220.9, 221.0, and 221.0 ppm with coupling constants J_{PC} of 24.4–26.4 Hz, while the resonance of the carboxamido carbon atoms give rise to a doublet centered at 200.4 ($J_{\text{PC}} = 39.0$ Hz), 201.1 ($J_{\text{PC}} = 45.8$ Hz), and 199.8 ppm ($J_{\text{PC}} = 37.8$ Hz), respectively. In the IR spectrum, the characteristic CO stretching frequency of the CO ligand and the carboxamido unit was observed at 1937, 1919, and 1914 cm^{-1} and 1617, 1605, and 1618 cm^{-1} , respectively. For comparison, the IR stretching frequency of the carboxamido unit in $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NNMe}_2-\text{PPh}_2)]$ was found at 1642 cm^{-1} [11].

Complex **1a** adopts a typical three legged piano stool conformation with the C and P atoms of the $\text{C}(\text{=O})\text{NiPr}-\text{PPh}_2$ moiety and the C atom of the CO ligand as the legs (Fig. 1). The $\text{Fe1}-\text{C}(\text{Cp})$ distance on average is 2.101(1) Å. The iron carbon bond distances $\text{Fe1}-\text{C6}$ and $\text{Fe1}-\text{C7}$ are 1.739(1) and 1.981(1) Å, respectively, the latter being typical for an iron carbon single bond. Thus, also in agreement with the NMR and IR spectroscopic data, **1a** is best described as a carboxamido complex (**A**) rather than an aminocarbene complex (**B**) (Scheme 7). The $\text{Fe1}-\text{P1}$ bond distance of 2.1773(3) Å is typical for iron phosphine complexes but slightly shorter than $\text{Fe1}-\text{P1} = 2.2223(4)$ Å in the parent complex **2** (Fig. 2). The $\text{C7}-\text{Fe1}-\text{P1}$ bite angle of the chelating $\text{C}(\text{=O})\text{NiPr}-\text{PPh}_2$ ligand is 69.43(4)°. For comparison, in the related complex $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NNMe}_2-\text{PPh}_2)]$ the bite angle is 70.5(1)°.

Since acyl and carbamoyl ligands are typically nucleophilic at the carbonyl oxygen, *i.e.*, resonance structure **B** may play a role, the reaction with carbon-based electrophiles may lead to aminocarbene complexes. It has to be kept in mind however that an electrophilic attack may occur also at the N atom of the carboxamido moiety resulting in P–N bond cleavage with concomitant N-alkylation.

Treatment of **1a** with $[\text{Me}_3\text{O}]\text{BF}_4$ (1 equiv) at room temperature for 4 h in CH_2Cl_2 as the solvent results in the formation of the azaphospha-carbene complex $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P}) = \text{C}(\text{OMe})-\text{NiPr}-\text{PPh}_2)]^+$ (**3**) in 58% isolated yield (Scheme 8). This class of complexes belongs to a rare series of transition metal complexes in which the carbene moiety is part of a four-membered chelate ligand coordinated in a $\kappa^2[\text{C},\text{P}]$ mode [6,7,12]. Complex **3** was characterized by elemental analysis and by ^1H , $^{13}\text{C}\{^1\text{H}\}$, and $^{31}\text{P}\{^1\text{H}\}$ NMR spectroscopy. Characteristic features comprise, in the $^{13}\text{C}\{^1\text{H}\}$ NMR spectrum, a marked low-field doublet resonance at 238.0 ppm ($d, J_{\text{CP}} = 34.8$ Hz) assignable to the carbene carbon atom of the four-membered azaphospha-carbene moiety. The carbonyl resonance gives rise to a doublet centered at 216.3 ppm ($d, J_{\text{CP}} = 22.2$ Hz). The $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum of **3** reveals a singlet at 115.0 ppm (*cf.* 111.6 ppm in **1a**).

On the other hand, protonation of **1a** with the Brønsted acid $[\text{HNEt}_3]^+$ led to clean formation of complex **2a** in 95% isolated yield (Scheme 8). Selective N-protonation took place which was associated with C–N bond cleavage and reformation of the CO and Ph_2PNHiPr ligands.

In search of related iron systems where carboxamido-phospha-ferracycles may also be formed via nucleophilic attack of a $\kappa^1(\text{P})$ -coordinated $\text{PR}_2\text{NHR}'$ ligand, we prepared complexes of the type *cis*-, *trans*-, *cis*-, *cis*- $[\text{Fe}(\text{CO})_2(\text{Ph}_2\text{PNHiPr})_2(\text{Br})_2]$ (**4a**) and *cis*-, *trans*-, *cis*-, *cis*- $[\text{Fe}(\text{CO})_2(\text{Ph}_2\text{PNH}t\text{Bu})_2(\text{Br})_2]$ (**4b**). These compounds were readily obtained as red, air stable solids by reacting *cis*- $[\text{Fe}(\text{CO})_4(\text{Br})_2]$ with 2 equivalents of the respective $\text{PR}_2\text{NHR}'$ ligands in 85 and 88% yield (Scheme 9) in CH_2Cl_2 at room temperature. In these complexes the CO and bromide ligands are in a mutual *cis* position, whereas the phosphine ligands are *trans* to one another.

Scheme 3. Aminophosphine ligands displaying various transformations to give unusual transition metal complexes.

Scheme 4. Intramolecular addition of the NHR' moiety of an aminophosphine ligand to coordinated CO.

Treatment of **4a** with 2 equivs of KOtBu in the presence of CO in THF at room temperature afforded the isomeric complexes *trans*- $[\text{Fe}(\text{CO})_2(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NiPr}-\text{PPh}_2)(\text{Ph}_2\text{PNHiPr})\text{Br}]$ (**5a**) and *cis*- $[\text{Fe}(\text{CO})_2(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NiPr}-\text{PPh}_2)(\text{Ph}_2\text{PNHiPr})\text{Br}]$ (**5a'**) in a roughly 5:1 ratio in 50% overall yield. In agreement with experimental data DFT/B3LYP calculations confirm that the isomer with a *trans* CO arrangement is slightly more stable by 2.5 kcal/mol (free energy) than the corresponding *cis* isomer. In the case of **4b** only one isomer, *viz trans*- $[\text{Fe}(\text{CO})_2(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NtBu}-\text{PPh}_2)(\text{Ph}_2\text{PNHtBu})\text{Br}]$ (**5b**), was formed in 40% yield (Scheme 9). These reactions again involve attack of the amido moiety of a deprotonated $\text{PR}_2\text{NHR}'$ ligand on coordinated CO. It has to be mentioned that the yields of **5a** and **5b** were independent of whether 1 or 2 equivs of KOtBu were used, i.e.,

complexes such as $[\text{Fe}(\text{CO})_2(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NiPr}-\text{PPh}_2)_2]$, were not observed. Complexes **5a** and **5b** are thermally robust red solids that are air stable in the solid state but slowly decompose in solution. Their identity was unequivocally established by ^1H , $^{13}\text{C}\{^1\text{H}\}$ and $^{31}\text{P}\{^1\text{H}\}$ NMR, IR spectroscopy, and elemental analysis.

In the $^{13}\text{C}\{^1\text{H}\}$ NMR spectrum of the major isomer **5a** the most noticeable resonances are a low-field signal of the two *trans* CO ligands observed as triplet centered at 212.4 ppm with a P–C coupling constants of 22.7 Hz. The resonance of the carboxamido moiety give rise to a doublet of doublets centered at 206.0 ppm with P–C couplings constant of 9.6 and 13.4 Hz. The $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum of **5a** reveals two doublets centered at 95.6 and 85.8 ppm with a large coupling constant of 84.7 Hz which is indicative for the phosphorus atoms being in a mutual *trans* position. Most ^1H and $^{13}\text{C}\{^1\text{H}\}$ NMR of resonances of the minor isomer **5a'** could not be reliably assigned since they were superimposed by the signals of the major isomer **5a**. In the $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum, however, **5a'** also exhibits two doublets centered at 94.8 (d, $J_{\text{PP}} = 115.9$ Hz) and 90.0 ppm (d, $J_{\text{PP}} = 115.9$ Hz). The large coupling constant again is consistent with a *trans*-P,P configuration. Similar NMR spectra were observed for **5b**, and are thus not discussed here. In the IR spectrum of **5a** and **5b** the two CO ligands give rise to two bands at 1966 and 1960 cm^{-1} (**5a**) and 1955 and 1950 cm^{-1} (**5b**) which can be assigned to the asymmetric CO stretching frequency (*cf* 2143 cm^{-1} in free CO). As expected the symmetric CO stretching frequency is IR

Fig. 1. Molecular structure of $[FeCp(CO)(\kappa^2(C,P)-(C=O)-NiPr-PPh_2)]$ (**1a**) showing 50% displacement ellipsoids. Selected distances and angles (\AA , $^\circ$): $\langle Fe1-C_{cp} \rangle = 2.101(1)$, $Fe1-P1$ 2.1773(3), $Fe1-C6$ 1.739(1), $Fe1-C7$ 1.981(1), $C6-O1$ 1.158(2), $C7-O2$ 1.219(2), $N1-C7$ 1.404(2), $P1-N1$ 1.6915(10), $C7-Fe1-P1$ 69.43(4), $Fe1-C7-O2$ 133.8(1), $Fe1-C7-N1$ 103.7(1), $Fe1-P1-N1$ 86.95(3), $P1-N1-C7$ 99.7(1).

Fig. 2. Molecular structure of **2** showing 50% displacement ellipsoids. Selected distances and angles (\AA , $^\circ$): $\langle Fe1-C_{cp} \rangle = 2.104(2)$, $Fe1-P1$ 2.2223(4), $Fe1-C6$ 1.780(2), $Fe1-C7$ 1.785(2), $C6-O1$ 1.141(2), $C7-O2$ 1.139(2), $P1-N1$ 1.6473(13), $N1-C20$ 1.477(2), $P1-Fe1-C6$ 90.73(5), $P1-Fe1-C7$ 93.83(5), $C6-Fe1-C7$ 96.28(7), $C20-N1-P1$ 125.14(10), $N1-Br1$ 3.3854(13).

Scheme 7. Resonance structures of complexes **1a-c**.

inactive which is also confirmed by DFT/B3LYP calculations. The appearance of two the resonances, which are only 5–6 cm^{-1} apart, may be due to intermolecular interactions, e.g. $C=O \cdots HN$ bonds, in the solid state [13]. The CO vibration of the carboxamido phosphacycle is shifted to lower wavenumbers observed at 1619 and 1616 cm^{-1} , respectively. The scaled calculated frequencies ν_{CO} together with the experimentally observed values are given in Table 1 and show a reasonably good agreement.

The molecular structure of complex **5a** was determined by X-ray crystallography. A structural view is depicted in Fig. 3 with selected bond distances and angles reported in the caption. The geometry about the metal center is distorted octahedral with the two phosphorus and carbon atoms in *trans* position and the bromide and carbon atom of carboxamido moiety atoms in *cis* position (Fig. 3). The $C32-Fe1-C33$ bond angle is $170.6(2)^\circ$. The chelate system $Fe1-P1-N1-(C31=O1)-Fe1$ resembles closely in bond lengths and bond angles the corresponding system in complex **1a**, except for the bond $Fe1-P1$, which is 2.1773(3) \AA in **1a** while it is 2.2480(9) \AA in **5a** due to the *trans*-influence of phosphorus P2 ($Fe1-P2 = 2.2651(9) \text{\AA}$). The short intramolecular hydrogen bond $N2-H2n \cdots O1$ in **5a** ($N2 \cdots O1 = 2.839(4) \text{\AA}$) has no effect on the bond angle $Fe1-C31-O1 = 134.2(2)^\circ$ as evident from the corresponding angle $133.8(1)^\circ$ in complex **1a** which lacks this interaction.

3. Conclusion

In the present study iron(II) complexes featuring one or two aminophosphine ligands of the type PR_2NHR' with $R = Ph, iPr$ and $R = tBu, Cy$ were synthesized. We demonstrated that upon treatment of $[FeCp(CO)_2X]$ ($X = Cl, Br$) with the anionic amidophosphine ligands $[R_2PNR']^-$, or upon deprotonation of the PR_2NHR' ligand in complexes $[FeCp(CO)_2(PR_2NHR'_2)]^+$ and *cis,trans,cis*- $[Fe(CO)_2(Ph_2PNHR')_2(Br)_2]$ complexes featuring four-membered carboxamido-phospha-ferracycles were obtained. In the course of these reactions the highly nucleophilic amido nitrogen atom reacted readily in an intramolecular fashion with the electrophilic carbon atom of a CO ligand. We have further demonstrated that the carboxamido-phospha-ferracycles react with the carbon-based electrophile $[Me_3O]^+$ to afford an aza-phospha-carbene. This is a

Scheme 8. Reactivity of complex **1a** toward the electrophile $[\text{Me}_3\text{O}]\text{BF}_4^-$ and the base NET_3 .

relatively rare type of transition metal complexes in which the carbene moiety is part of a four-membered chelate ligand coordinated in a $\kappa^2(\text{C},\text{P})$ mode. In the presence of protons, the carboxamido-phospha-ferracycle underwent clean C–N bond cleavage thereby reforming the starting complex $[\text{FeCp}(\text{CO})_2(\text{PR}_2\text{NHR})_2]^+$.

4. Experimental

4.1. General

All manipulations were performed under an inert atmosphere of argon by using Schlenk techniques. The solvents were purified according to standard procedures [14]. The ligands $\text{PPh}_2\text{NH}i\text{Pr}$, $\text{PPh}_2\text{NH}t\text{Bu}$, and PPh_2NHCy [15] and the complexes $[\text{FeCp}(\text{CO})_2\text{Cl}]$, of $[\text{FeCp}(\text{CO})_2\text{Br}]$ [16], and $\text{cis-}[\text{Fe}(\text{CO})_4\text{Br}_2]$ [17] were prepared according to the literature. The deuterated solvents were purchased from Aldrich and dried over 4 Å molecular sieves [1]. ^1H , $^{13}\text{C}\{^1\text{H}\}$, and $^{31}\text{P}\{^1\text{H}\}$ NMR spectra were recorded on Bruker AVANCE-250 and AVANCE-300 DPX spectrometers and were referenced to SiMe_4 and H_3PO_4 (85%), respectively.

4.2. Syntheses

4.2.1. $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NiPr}-\text{PPh}_2)]$ (**1a**)

A solution of $\text{PPh}_2\text{NH}i\text{Pr}$ (300 mg, 1.23 mmol) in THF (20 mL) was cooled to -20°C and $n\text{BuLi}$ (500 μL , 1.23 mmol, 2.5 M solution in n -hexane) was slowly added. The solution was stirred for 2 h at -20°C and an additional hour at room temperature. After that, $[\text{FeCp}(\text{CO})_2\text{Cl}]$ (262 mg, 1.23 mmol) was added and the mixture was stirred for 8 h at room temperature. The solvent was then removed under reduced pressure. The residue was redissolved in toluene (10 mL) and the solution was filtered through Celite. After removal of the solvent under reduced pressure, an orange solid was obtained which was washed with n -pentane (10 mL) and dried under vacuum. Yield: 207 mg (40%). Anal. calcd. for $\text{C}_{22}\text{H}_{22}\text{FeNO}_2\text{P}$: C, 63.03; H, 5.29; N, 3.34. Found: C, 63.09; H, 5.12; N, 3.28. ^1H NMR (δ , CDCl_3 , 20°C): 7.87 (m, 4H, Ph), 7.51 (m, 6H, Ph), 4.38 (s, 5H, Cp), 3.49 (m, 1H, $\text{CH}(\text{CH}_3)_2$), 1.29 (d, $J = 5.8$ Hz, 3H, $\text{CH}(\text{CH}_3)_2$), 0.99 (d,

$J = 6.7$ Hz, 3H, $\text{CH}(\text{CH}_3)_2$). $^{13}\text{C}\{^1\text{H}\}$ NMR (δ , CDCl_3 , 20°C): 220.9 (d, $J_{\text{PC}} = 26.0$ Hz, CO), 200.4 (d, $J_{\text{PC}} = 39.0$ Hz, NCO), 137.2 (d, $J_{\text{PC}} = 40.6$ Hz, Ph), 133.8 (d, $J_{\text{PC}} = 13.5$ Hz, Ph), 131.8 (d, $J_{\text{PC}} = 2.7$ Hz, Ph), 130.7 (d, $J_{\text{PC}} = 13.5$ Hz, Ph), 130.4 (d, $J_{\text{PC}} = 2.7$ Hz, Ph), 128.6 (d, $J_{\text{PC}} = 9.5$ Hz, Ph), 128.4 (d, $J_{\text{PC}} = 7.5$ Hz, Ph), 82.1 (s, Cp), 50.7 (d, $J_{\text{PC}} = 8.1$ Hz, $\text{CH}(\text{CH}_3)_2$), 23.0 (s, $\text{CH}(\text{CH}_3)_2$), 21.4 (s, $\text{CH}(\text{CH}_3)_2$). $^{31}\text{P}\{^1\text{H}\}$ NMR (δ , CDCl_3 , 20°C): 111.6. IR (ATR, 25°C): 1937 ($\nu_{\text{C}=\text{O}}$), 1617 ($\nu_{\text{C}=\text{O}}$).

4.2.2. $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{N}t\text{Bu}-\text{PPh}_2)]$ (**1b**)

This complex was prepared analogously to **1a** with $[\text{FeCp}(\text{CO})_2\text{Cl}]$ (400 mg, 1.55 mmol) and $\text{Ph}_2\text{PNH}t\text{Bu}$ (400 mg, 1.55 mmol), and $n\text{BuLi}$ (630 μL , 1.48 mmol, 2.5 M solution in n -hexane) as starting materials. Yield: 335 mg (50%). Anal. calcd for $\text{C}_{23}\text{H}_{24}\text{FeNO}_2\text{P}$: C, 63.76; H, 5.58; N, 3.23. Found: C, 63.66; H, 5.63; N, 3.19. ^1H NMR (δ , CDCl_3 , 20°C): 7.90 (m, 4H, Ph), 7.48 (m, 6H, Ph), 4.39 (s, 5H, Cp), 1.20 (s, 9H, $\text{C}(\text{CH}_3)_3$). $^{13}\text{C}\{^1\text{H}\}$ NMR (δ , CDCl_3 , 20°C): 221.0 (d, $J_{\text{PC}} = 24.4$ Hz, CO), 201.1 (d, $J_{\text{PC}} = 45.8$ Hz, NCO), 136.4 (d, $J_{\text{PC}} = 39.3$ Hz, Ph), 133.8 (d, $J_{\text{PC}} = 41.3$ Hz, Ph), 132.7 (d, $J_{\text{PC}} = 12.5$ Hz, Ph), 131.2 (d, $J_{\text{PC}} = 3.2$ Hz, Ph), 130.7 (d, $J_{\text{PC}} = 11.7$ Hz, Ph), 130.3 (d, $J_{\text{PC}} = 3.2$ Hz, Ph), 128.6 (d, $J_{\text{PC}} = 7.4$ Hz, Ph), 128.4 (d, $J_{\text{PC}} = 5.8$ Hz, Ph), 82.8 (s, Cp), 65.8 (s, $\text{CH}(\text{CH}_3)_2$), 29.5 (s, $\text{CH}(\text{CH}_3)_2$). $^{31}\text{P}\{^1\text{H}\}$ NMR (δ , CDCl_3 , 20°C): 113.0. IR (ATR, 25°C): 1919 ($\nu_{\text{C}=\text{O}}$), 1605 ($\nu_{\text{C}=\text{O}}$).

4.2.3. $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NCy}-\text{PiPr}_2)]$ (**1c**)

This complex was prepared analogously to **1a** with $[\text{FeCp}(\text{CO})_2\text{Cl}]$ (370 mg, 1.75 mmol), Ph_2PNHCy (376 mg, 1.75 mmol), and $n\text{BuLi}$ (700 μL , 1.75 mmol, 2.5 M solution in n -hexane) as starting materials. Yield: 307 mg (45%). Anal. calcd for $\text{C}_{19}\text{H}_{30}\text{FeNO}_2\text{P}$: C, 58.48; H, 7.49; N, 3.59. Found: C, 58.53; H, 7.40; N, 3.62. ^1H NMR (δ , CDCl_3 , 20°C): 4.61 (s, 5H, Cp), 2.93 (m, 1H, NCH), 2.54 (m, 1H, $\text{CH}(\text{CH}_3)_2$), 2.18 (m, 1H, $\text{CH}(\text{CH}_3)_2$), 1.69 (bs, 4H, Cy), 1.53 (bs, 6H, Cy), 1.32 (d, $J = 11.0$ Hz, 3H, $\text{CH}(\text{CH}_3)_2$), 1.30 (s, 1H, Cy), 1.25 (d, $J = 7.3$ Hz, 3H, $\text{CH}(\text{CH}_3)_2$). $^{13}\text{C}\{^1\text{H}\}$ NMR (δ , CDCl_3 , 20°C): 221.0 (d, $J_{\text{PC}} = 26.4$ Hz, CO), 199.8 (d, $J_{\text{PC}} = 37.8$ Hz, NCO), 80.8 (s, Cp), 58.5 (d, $J_{\text{PC}} = 8.1$ Hz, NC), 32.7 (d, $J_{\text{PC}} = 71.9$ Hz, $\text{CH}(\text{CH}_3)_2$), 30.6 (d, $J_{\text{PC}} = 19.3$ Hz, Cy), 27.9 (d, $J_{\text{PC}} = 15.9$ Hz, Cy), 26.8 (s, Cy), 25.3 (s, Cy), 20.4 (d, $J_{\text{PC}} = 5.7$ Hz, $\text{CH}(\text{CH}_3)_2$), 18.7 (s, Cy), 18.0 (d, $J_{\text{PC}} = 5.74$ Hz, $\text{CH}(\text{CH}_3)_2$). $^{31}\text{P}\{^1\text{H}\}$

Exptl.	Not observed	1966/1960	1616

NMR (δ , CDCl_3 , 20 °C): 140.0. IR (ATR, 25 °C): 1914 ($\nu_{\text{C=O}}$), 1618 ($\nu_{\text{C=O}}$).

4.2.4. $[\text{FeCp}(\text{CO})_2(\text{Ph}_2\text{PNHiPr})]\text{Br}$ (**2**)

To a solution of $[\text{FeCp}(\text{CO})_2\text{Br}]$ (1.00 g, 3.89 mmol) in THF (10 mL) Ph_2PNHiPr (995 mg, 4.01 mmol) was added and the reaction mixture was stirred overnight at room temperature. Removal of the solvent afforded **2** as a yellow solid. Yield: 1.75 g (90%). Anal. calcd for $\text{C}_{22}\text{H}_{23}\text{BrFeNO}_2\text{P}$: C, 52.94; H, 4.44; N, 2.81. Found: C, 53.04; H, 4.39; N, 2.85. ^1H NMR (δ , CDCl_3 , 20 °C): 7.61–7.53 (m, 10H, Ph), 5.96 (d, $J = 10.2$ Hz, 1H, NH), 5.27 (s, 5H, Cp), 2.99 (bs, 1H, $\text{CH}(\text{CH}_3)_2$), 1.16 (d, $J = 5.4$ Hz, 6H, $\text{CH}(\text{CH}_3)_2$). $^{13}\text{C}\{^1\text{H}\}$ NMR (δ , CDCl_3 , 20 °C): 210.3 (d, $J_{\text{PC}} = 27.1$ Hz, CO), 135.0 (d, $J_{\text{PC}} = 59.1$ Hz, Ph), 131.7 (d, $J_{\text{PC}} = 10.4$ Hz, Ph), 131.3 (d, $J_{\text{PC}} = 10.7$ Hz, Ph), 129.0 (d, $J_{\text{PC}} = 10.9$ Hz, Ph), 88.7 (s, Cp), 48.8 (d, $J_{\text{PC}} = 9.6$ Hz, $\text{CH}(\text{CH}_3)_2$), 24.8 (d, $J_{\text{PC}} = 3.52$ Hz, $\text{CH}(\text{CH}_3)_2$). $^{31}\text{P}\{^1\text{H}\}$ NMR (δ , CDCl_3 , 20 °C): 100.6. IR (ATR, 25 °C): 2040 ($\nu_{\text{C=O}}$), 1993 ($\nu_{\text{C=O}}$).

4.2.5. $[\text{FeCp}(\text{CO})_2(\text{Ph}_2\text{PNHiPr})]\text{BF}_4$ (**2'**)

This complex was prepared analogously to **2** with $[\text{FeCp}(\text{CO})_2\text{Br}]$ (350 mg, 1.65 mmol) and Ph_2PNHiPr (400 mg, 1.65 mmol) as starting materials but in the presence of NaBF_4 (182 mg, 1.65 mmol). Yield: 600 mg (72%). Anal. calcd for $\text{C}_{22}\text{H}_{23}\text{BF}_4\text{FeNO}_2\text{P}$: C, 52.11; H, 4.17; N, 2.76. Found: C, 52.14; H, 4.08; N, 2.80. NMR and IR spectra were identical to those of **2**.

4.2.6. Reaction of $[\text{FeCp}(\text{CO})_2(\text{Ph}_2\text{PNHiPr})]\text{BF}_4$ with KOTu .

Formation of $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NiPr}-\text{PPh}_2)]$ (**1a**)

A solution of $[\text{FeCp}(\text{CO})_2(\text{Ph}_2\text{PNHiPr})]\text{BF}_4$ (**2a'**) (220 mg, 0.44 mmol) in THF (10 mL) was treated with KOTu (55 mg, 0.48 mmol) and was stirred for 8 h. The solvent was removed under vacuum and the crude product was redissolved in toluene and

filtered through Celite. After removal of the solvent under reduced pressure, **1a** was obtained which was washed with *n*-pentane (10 mL) and dried under vacuum. Yield: 87 mg (48%).

4.2.7. $[\text{FeCp}(\text{CO})(\kappa^2(\text{C},\text{P})=\text{C}(\text{OMe})-\text{NiPr}-\text{PPh}_2)]\text{BF}_4$ (**3**)

A solution of **1a** (500 mg, 1.19 mmol) in CH_2Cl_2 (10 mL) was treated with $[\text{Me}_3\text{O}]\text{BF}_4$ (177 mg, 1.19 mmol). After stirring for 4 h, insoluble materials were removed by filtration through Celite. On removal of the solvent, **3** was obtained as an orange solid which was washed with *n*-hexane, and dried under vacuum. Yield: 360 mg (58%). Anal. calcd for $\text{C}_{35}\text{H}_{39}\text{BBrF}_4\text{FeN}_2\text{O}_3\text{P}$: C, 53.27; H, 4.98; N, 3.55. Found: C, 53.19; H, 4.89; N, 3.64. ^1H NMR (δ , CDCl_3 , 20 °C): 7.58 (m, 10H, Ph), 4.80 (s, 5H, Cp), 4.33 (s, 3H, OCH_3), 3.93 (m, 1H, $\text{CH}(\text{CH}_3)_2$), 1.40 (d, $J = 6.4$ Hz, 3H, $\text{CH}(\text{CH}_3)_2$), 0.92 (d, $J = 6.4$ Hz, 3H, $\text{CH}(\text{CH}_3)_2$). $^{13}\text{C}\{^1\text{H}\}$ NMR (δ , CDCl_3 , 20 °C): 238.0 (d, $J_{\text{PC}} = 34.8$ Hz, $\text{Fe}=\text{C}$), 216.3 (d, $J_{\text{PC}} = 22.2$ Hz, CO), 134.7 (d, $J_{\text{PC}} = 22.3$ Hz, Ph), 134.4 (d, $J_{\text{PC}} = 14.2$ Hz, Ph), 134.2 (d, $J_{\text{PC}} = 22.2$ Hz, Ph), 132.8 (d, $J_{\text{PC}} = 2.59$ Hz, Ph), 131.9 (d, $J_{\text{PC}} = 2.5$ Hz, Ph), 131.3 (d, $J_{\text{PC}} = 11.1$ Hz, Ph), 129.9 (d, $J_{\text{PC}} = 11.3$ Hz, Ph), 83.1 (s, Cp), 64.9 (s, OCH_3), 55.8 (d, $J_{\text{PC}} = 5.5$ Hz, $\text{CH}(\text{CH}_3)_2$), 21.8 (s, $\text{CH}(\text{CH}_3)_2$), 20.8 (s, $\text{CH}(\text{CH}_3)_2$). $^{31}\text{P}\{^1\text{H}\}$ NMR (δ , CDCl_3 , 20 °C): 115.0. IR (ATR, 25 °C): 2004 ($\nu_{\text{C=O}}$).

4.2.8. Protonation of **1a** with $[\text{HNEt}_3]\text{Cl}$. Formation of **2**

A solution of **1a** (500 mg, 1.19 mmol) in CH_2Cl_2 (10 mL) was treated with $[\text{HNEt}_3]\text{Cl}$ (165 mg, 1.19 mmol). After stirring for 4h, insoluble materials were removed by filtration through Celite. On removal of the solvent, **2** was obtained as a yellow solid which was collected on a glass frit, washed with *n*-hexane, and dried under vacuum. Yield: 514 mg (95%).

4.2.9. *cis,trans,cis*- $[\text{Fe}(\text{CO})_2(\text{Ph}_2\text{PNHiPr})_2(\text{Br})_2]$ (**4a**)

To a solution of *cis*- $[\text{Fe}(\text{CO})_2\text{Br}_2]$ (1.00 g, 3.05 mmol) in CH_2Cl_2 (10 mL) Ph_2PNHiPr (1.52 g, 6.25 mmol) was added at 0 °C and the mixture was stirred overnight at room temperature. The solution was then filtered through Celite. After removal of the solvent under reduced pressure, an orange solid was obtained which was washed with diethyl ether (10 mL) and dried under vacuum. Yield: 1.96 g (85%). Anal. calcd for $\text{C}_{32}\text{H}_{36}\text{Br}_2\text{FeN}_2\text{O}_2\text{P}_2$: C, 50.69; H, 4.79; N, 3.69. Found: C, 50.72; H, 4.86; N, 3.60. ^1H NMR (δ , CDCl_3 , 20 °C): 7.99 (bs, 8H, Ph), 7.48 (bs, 12H, Ph), 3.42 (bs, 2H, NH), 2.29 (m, 2H, $\text{CH}(\text{CH}_3)_2$), 0.91 (d, $J_{\text{PC}} = 6.3$ Hz, 12H, $\text{CH}(\text{CH}_3)_2$). $^{13}\text{C}\{^1\text{H}\}$ NMR (δ , CDCl_3 , 20 °C): 212.7 (t, $J_{\text{PC}} = 22.7$ Hz, CO), 133.6 (d, $J_{\text{PC}} = 25$ Hz, Ph), 133.0 (dd, $J_{\text{PC}} = 5.1$ Hz, Ph), 131.7 (dd, $J_{\text{PC}} = 5.4$ Hz, Ph), 130.8 (s, Ph), 127.9 (dd, $J_{\text{PC}} = 4.6$ Hz, Ph), 46.4 (dd, $J_{\text{PC}} = 4.9$ Hz, $\text{CH}(\text{CH}_3)_2$), 24.7 (s, $\text{CH}(\text{CH}_3)_2$). $^{31}\text{P}\{^1\text{H}\}$ NMR (δ , CDCl_3 , 20 °C): 80.6. IR (ATR, 25 °C): 2041 ($\nu_{\text{C=O}}$), 1986 ($\nu_{\text{C=O}}$).

4.2.10. *cis,trans,cis*- $[\text{Fe}(\text{CO})_2(\text{Ph}_2\text{PNHtBu})_2(\text{Br})_2]$ (**4b**)

This complex was prepared analogously to **4a** with *cis*- $[\text{Fe}(\text{CO})_2\text{Br}_2]$ (845 mg, 2.58 mmol) and Ph_2PNHtBu (1.33 g, 5.16 mmol) as starting materials. Yield: 1.7 mg (88%). Anal. calcd for $\text{C}_{34}\text{H}_{40}\text{Br}_2\text{FeN}_2\text{O}_2\text{P}_2$: C, 51.94; H, 5.13; N, 3.56. Found: C, 52.04; H, 5.20; N, 3.46. ^1H NMR (δ , acetone- d_6 , 20 °C): 8.36 (bs, 8H, Ph), 7.48 (bs, 12H, Ph), 3.7 (bs, 2H, NH), 0.87 (s, 18H, $\text{C}(\text{CH}_3)_3$). $^{13}\text{C}\{^1\text{H}\}$ NMR (δ , CDCl_3 , 20 °C): 213.3 (t, $J_{\text{PC}} = 24.0$ Hz, CO), 134.2 (dd, $J_{\text{PC}} = 25.7$ Hz, Ph), 133.5 (dd, $J_{\text{PC}} = 5.3$ Hz, Ph), 130.7 (s, Ph), 127.7 (dd, $J_{\text{PC}} = 4.7$ Hz, Ph), 55.5 (s, $\text{C}(\text{CH}_3)_3$), 31.7 (s, $\text{C}(\text{CH}_3)_3$). $^{31}\text{P}\{^1\text{H}\}$ NMR (δ , acetone- d_6 , 20 °C): 72.2. IR (ATR, 25 °C): 2035 ($\nu_{\text{C=O}}$), 1980 ($\nu_{\text{C=O}}$).

4.2.11. *trans*- $[\text{Fe}(\text{CO})_2(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NiPr}-\text{PPh}_2)(\text{Ph}_2\text{PNHiPr})\text{Br}]$ (**5a**) and *cis*- $[\text{Fe}(\text{CO})_2(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NiPr}-\text{PPh}_2)(\text{Ph}_2\text{PNHiPr})\text{Br}]$ (**5a'**)

A Schlenk tube was charged with **4a** (400 mg, 0.53 mmol) and KOTu (122 mg, 1.06 mmol). Under a CO atmosphere THF (10 mL) was added and the mixture was stirred overnight at room

Fig. 3. Molecular structure of *trans*- $[\text{Fe}(\text{CO})_2(\kappa^2(\text{C},\text{P})-(\text{C}=\text{O})-\text{NiPr}-\text{PPh}_2)(\text{Ph}_2\text{PNHiPr})\text{Br}]$ (**5a**) (major isomer) showing 40% displacement ellipsoids. temperature. The red solution was then filtered through Celite and the solvent was removed under reduced pressure. The residue was redissolved in CH₂Cl₂. Insoluble materials were removed by filtration. After evaporation of the solvent *in vacuo*, a red solid was obtained which was washed with *n*-pentane (10 mL) and dried under vacuum. Yield: 185 mg (50%). Anal. calcd for C₃₃H₃₅BrFeN₂O₃P₂: C, 56.19; H, 5.00; N, 3.97. Found: C, 56.00; H, 5.12, N, 4.01. Major isomer: ¹H NMR (δ, CDCl₃, 20 °C): 7.85 (d, *J* = 6.79 Hz, 8H, Ph), 7.50 (d, *J* = 8.38 Hz, 8H, Ph), 7.43 (s, 4H, Ph), 4.70 (bs, 1H, NH), 3.46 (m, 1H, CH(CH₃)₂), 3.12 (m, 1H, CH(CH₃)₂), 1.31 (d, *J* = 6.4 Hz, 6H, CH(CH₃)₂), 0.94 (d, *J* = 6.4 Hz, 6H, CH(CH₃)₂). ¹³C{¹H} NMR (δ, CDCl₃, 20 °C): 212.4 (t, *J*_{PC} = 22.7 Hz, CO), 206.0 (dd, *J*_{PC} = 9.6 Hz, *J*_{PC} = 13.4 Hz, NCO), 135.1 (d, *J*_{PC} = 37.5 Hz, Ph), 133.3 (d, *J*_{PC} = 12.1 Hz, Ph), 133.1 (d, *J*_{PC} = 13.5 Hz, Ph), 131.8 (s, Ph), 130.2 (s, Ph), 128.7 (d, *J*_{PC} = 11.1 Hz, Ph), 128.0 (d, *J*_{PC} = 11.1 Hz, Ph), 45.7 (t, *J*_{PC} = 12.7 Hz, Ph), 25.5 (s, CH(CH₃)₂), 22.0 (s, CH(CH₃)₂). ³¹P{¹H} NMR (δ, CDCl₃, 20 °C): 95.6 (d, *J*_{PP} = 84.7 Hz), 85.8 (d, *J*_{PP} = 84.7 Hz). IR (ATR, 25 °C): 1966 (ν_{C=O}), 1960 (ν_{C=O}), 1616 (ν_{C=O}). Minor isomer *cis*-[Fe(CO)₂(κ²(C,P)-(C=O)-NiPr-PPh₂)(Ph₂PNHiPr)Br] (**5a'**): Most ¹H and ¹³C NMR resonances are superimposed by the signals of the major isomer and could not reliably assigned. ³¹P{¹H} NMR (δ, CDCl₃, 20 °C): 94.8 (d, *J*_{PP} = 115.9 Hz), 90.0 (d, *J*_{PP} = 115.9 Hz).

4.2.12. *trans*-[Fe(CO)₂(κ²(C,P)-(C=O)-NtBu-PPh₂)(Ph₂PNHtBu)Br] (**5b**)

This complex was prepared analogously to **5a** with **4b** (0.70 g, 0.89 mmol) as starting material. Yield: 260 mg (40%). Anal. calcd for C₃₅H₃₉BrFeN₂O₃P₂: C, 57.32; H, 5.36; N, 3.82. Found: C, 57.40; H, 5.29; N, 3.79. ¹H NMR (δ, CDCl₃, 20 °C): 7.98 (bs, 8H, Ph), 7.42 (bs, 2H, Ph), 4.84 (bs, 1H, NH), 3.46 (m, 1H, CH(CH₃)₂), 1.28 (s, 9H, C(CH₃)₃), 1.05 (s, 9H, C(CH₃)₃). ¹³C{¹H} NMR (δ, CDCl₃, 20 °C): 213.3 (dd, *J*_{PC} = 23.4 Hz, *J*_{PC} = 22.9 Hz CO), 206.0 (dd, *J*_{PC} = 9.6 Hz, *J*_{PC} = 13.4 Hz, NCO), 136.2 (d, *J*_{PC} = 47.7 Hz, Ph), 136.1 (d, *J*_{PC} = 47.7 Hz, Ph), 134.5 (d, *J*_{PC} = 10.8 Hz, Ph), 132.8 (d, *J*_{PC} = 10.8 Hz,

Ph), 132.6 (d, *J*_{PC} = 11.6 Hz, Ph), 131.4 (d, *J*_{PC} = 2.3 Hz, Ph), 129.9 (d, *J*_{PC} = 2.3 Hz, Ph), 128.5 (d, *J*_{PC} = 10.6 Hz, Ph), 127.6 (d, *J*_{PC} = 10.0 Hz, Ph), 62.3 (d, *J*_{PC} = 7.6 Hz, C(CH₃)₃), 55.9 (d, *J*_{PC} = 13.9 Hz, C(CH₃)₃), 32.1 (d, *J*_{PC} = 3.1 Hz, C(CH₃)₃), 29.5 (d, *J*_{PC} = 1.5 Hz, C(CH₃)₃). ³¹P{¹H} NMR (δ, CDCl₃, 20 °C): 90.4 (d, *J*_{PP} = 79.3 Hz), 87.3 (d, *J*_{PP} = 79.3 Hz). IR (ATR, 25 °C): 1955 (ν_{C=O}), 1950 (ν_{C=O}), 1619 (ν_{C=O}).

4.3. X-ray structure determinations

Single crystals for X-ray diffraction were obtained as follows: [FeCp(CO)(κ²(C,P)-(C=O)-NiPr-PPh₂)] (**1a**), by vapor diffusion of *n*-pentane into a THF solution, [FeCp(CO)₂(Ph₂PNHiPr)Br] (**2**) by vapor diffusion of Et₂O into a CH₂Cl₂ solution; *trans/cis*-[Fe(CO)₂(κ²(C,P)-(C=O)-NiPr-PPh₂)(Ph₂PNHiPr)Br] (**5a/5a'**) by vapor diffusion of Et₂O into a CH₂Cl₂ solution. The color of the crystals varied from orange to red brown. X-ray diffraction data were collected at *T* = 100 K on a Bruker Kappa APEX-2 CCD diffractometer with an Oxford Cryosystems cooler using graphite-monochromatized Mo-Kα radiation (λ = 0.71073 Å) and fine sliced φ- and ω-scans covering complete spheres of the reciprocal space. After data integration with program SAINT corrections for absorption and detector effects were applied with the program SADABS [18] The structures were solved by direct methods (SHELXS97) and refined on *F* [2] with the program SHELXL97 [19] Non-hydrogen atoms were refined anisotropically. Most H atoms were placed in calculated positions and thereafter refined as riding. In (**5a**) Br was partly substituted by CO and vice versa (84% *trans*- and 16% in *cis*-dicarbonyl configuration), and the subordinately occupied sites were refined with distance and displacement parameter restraints. All crystal structures were checked with the program PLATON [20] Molecular graphics was generated with program MERCURY [21] Crystal data and experimental details are given in Table 2.

4.4. Computational details

Calculations were performed using the GAUSSIAN 09 software package [22], and the B3LYP functional [23] without symmetry constraints. The optimized geometries were obtained with the Stuttgart/Dresden ECP (SDD) basis set [24] to describe the electrons of the iron atom. For all other atoms the 6–31g** basis set was employed [25]. Frequency calculations were performed to confirm the nature of the stationary points. A scaling factor of 0.9521 was applied for the CO frequencies [26].

S Supporting Information

ABSTRACT: In the present study the Mo(0) and W(0) complexes $[M(\text{PNP})(\text{CO})_3]$ as well as seven-coordinate cationic hydridocarbonyl Mo(II) and W(II) complexes of the type $[M(\text{PNP})(\text{CO})_3\text{H}]^+$, featuring PNP pincer ligands based on 2,6-diaminopyridine, have been prepared and fully characterized. The synthesis of Mo(0) complexes $[\text{Mo}(\text{PNP})(\text{CO})_3]$ was accomplished by treatment of $[\text{Mo}(\text{CO})_3(\text{CH}_3\text{CN})_3]$ with the respective PNP ligands. The analogous W(0) complexes were prepared by reduction of the bromocarbonyl complexes $[\text{W}(\text{PNP})(\text{CO})_3\text{Br}]^+$ with NaHg. These intermediates were obtained from the known dinuclear complex $[\text{W}(\text{CO})_4(\mu\text{-Br})\text{Br}]_2$, prepared in situ from $\text{W}(\text{CO})_6$ and stoichiometric amounts of Br_2 . Addition of HBF_4 to $[M(\text{PNP})(\text{CO})_3]$ resulted in clean protonation at the molybdenum and tungsten centers to generate the Mo(II) and W(II) hydride complexes $[M(\text{PNP})(\text{CO})_3\text{H}]^+$. The protonation is fully reversible, and upon addition of NEt_3 as base the Mo(0) and W(0) complexes $[M(\text{PNP})(\text{CO})_3]$ are regenerated quantitatively. All heptacoordinate complexes exhibit fluxional behavior in solution. The mechanism of the dynamic process of the hydrido carbonyl complexes was investigated by means of DFT calculations, revealing that it occurs in a single step. The structures of representative complexes were determined by X-ray single-crystal analyses.

INTRODUCTION

Tridentate PNP ligands in which the central pyridine-based ring donor contains $-\text{CH}_2\text{PR}_2$ substituents in the two ortho positions are widely utilized ligands in transition-metal chemistry (e.g., Fe, Ru, Rh, Ir, Pd, Pt).^{1–10} As part of our effort to create tridentate PNP pincer-type ligands in which the steric, electronic, and stereochemical properties can be easily varied, we have recently described the synthesis of a series of modularly designed PNP ligands based on N-heterocyclic diamines and $\text{R}_2\text{P}(\text{O})\text{R}'$ which contain both bulky and electron-rich dialkylphosphines as well as various P–O bond containing achiral and chiral phosphine units.¹¹ In these PNP ligands the central pyridine ring contains $-\text{NR}'\text{PR}_2$ ($\text{R}' = \text{H}$, alkyl, $\text{R} = \text{alkyl}$, aryl) substituents in the two ortho positions. This methodology was first developed for the synthesis of *N,N'*-bis(diphenylphosphino)-2,6-diaminopyridine (PNP-Ph).¹²

With these types of PNP ligands, we have thus far studied their reactivity toward different transition-metal fragments, which resulted in the preparation of a range of new pincer transition-metal complexes, including several new square-planar

Ni(II), Pd(II), and Pt(II) PNP complexes,¹³ various iron complexes acting as CO sensors¹⁴ and catalysts for the coupling of aromatic aldehydes with ethyldiazoacetate,¹⁵ and several pentacoordinated nickel complexes.¹⁶ Surprisingly, as far as group 6 PNP complexes are concerned, only a few examples have been described in the literature. A few years ago Haupt and co-workers reported the synthesis of $[M(\text{PNP-Ph})(\text{CO})_3]$ ($\text{M} = \text{Cr}, \text{Mo}, \text{W}$),¹² while Walton and co-workers described the synthesis of the dinuclear molybdenum complex $[\text{Mo}(\text{PNP})\text{Mo}(\text{HPCy}_2)\text{Cl}_3]$ (PNP = 2,6-bis-(dicyclohexylphosphinomethyl)pyridine).¹⁷ Most recently, dinuclear molybdenum and tungsten dinitrogen complexes bearing bulky PNP pincer ligands were found to work as effective catalysts for the formation of ammonia from dinitrogen.¹⁸ Finally, Templeton and co-workers described the synthesis of a series of hydrido carbonyl and halo carbonyl tungsten pincer complexes featuring the silazane-based PNP

pincer-type ligand $\text{HN}(\text{SiMe}_2\text{CH}_2\text{PPh}_2)_2$.¹⁹ In a preliminary study we have prepared cationic seven-coordinate halo carbonyl molybdenum pincer complexes of the types $[\text{Mo}(\text{PNP}-i\text{Pr})(\text{CO})_3\text{I}]^+$ and $[\text{Mo}(\text{PNP}-i\text{Pr})(\text{CO})_2(\text{CH}_3\text{CN})\text{I}]^+$.¹³ Here we report on the synthesis, characterization, and reactivity of a series of new hydrido carbonyl molybdenum(II) and tungsten(II) PNP pincer complexes.²⁰

RESULTS AND DISCUSSION

Molybdenum(0) and Tungsten(0) Complexes. We have recently reported the synthesis of molybdenum tricarbonyl complexes of the type $[\text{Mo}(\text{PNP})(\text{CO})_3]$ (**2a–c**) by reacting $[\text{Mo}(\text{CO})_3(\text{CH}_3\text{CN})_3]$, prepared in situ by refluxing a solution of $[\text{Mo}(\text{CO})_6]$ in CH_3CN for 4 h, with the PNP ligands PNP-Ph (**1a**), PNP-*i*Pr (**1b**), and PNP-*t*Bu (**1c**) in 74–90% isolated yields.¹³ The same procedure was followed with the N-methylated PNP ligand $\text{PNP}^{\text{Me}}-i\text{Pr}$ (**1d**), affording $[\text{Mo}(\text{PNP}^{\text{Me}}-i\text{Pr})(\text{CO})_3]$ (**2d**) in 80% yield (Scheme 1). The new

Scheme 1

PNP ligand **1d** was prepared in a three-step procedure involving borane protection of the phosphine, a deprotonation/alkylation step, and deprotection of the phosphine, as shown in Scheme 2. The analogous tungsten complexes

Scheme 2

$[\text{W}(\text{PNP})(\text{CO})_3]$ can be prepared in a similar fashion but require much longer reaction times (several days to prepare the intermediate $[\text{W}(\text{CO})_3(\text{CH}_3\text{CN})_3]$); moreover, the yields turned out to be significantly lower (10–25%). It has to be noted that already a few years ago Haupt and co-workers reported the synthesis of $[\text{M}(\text{PNP}-\text{Ph})(\text{CO})_3]$ ($\text{M} = \text{Mo}, \text{W}$) in 34 and 22% yields.¹² We thus developed an alternative method to obtain tungsten(0) complexes $[\text{W}(\text{PNP})(\text{CO})_3]$ via the intermediacy of the known dinuclear complex $[\text{W}(\text{CO})_4(\mu\text{-Br})\text{Br}]_2$,²¹ prepared in situ from $\text{W}(\text{CO})_6$ and stoichiometric amounts of Br_2 in CH_2Cl_2 at -70°C . Treatment of a solution

of $[\text{W}(\text{CO})_4(\mu\text{-Br})\text{Br}]_2$ in CH_2Cl_2 at room temperature with the PNP ligands **1a–c** afforded on workup the seven-coordinate tungsten(II) complexes $[\text{W}(\text{PNP})(\text{CO})_3\text{Br}]\text{Br}$ (**3a–c**) in 60–80% yields (Scheme 3).

It has to be noted that the reaction of PNP ligands with $[\text{Mo}(\text{CO})_4(\mu\text{-Br})\text{Br}]_2$,²¹ prepared in situ from $\text{Mo}(\text{CO})_6$ and Br_2 in CH_2Cl_2 at -70°C , affords the analogous seven-coordinate molybdenum complexes $[\text{Mo}(\text{PNP})(\text{CO})_3\text{Br}]\text{Br}$. This has been demonstrated for the synthesis of $[\text{Mo}(\text{PNP}-\text{Ph})(\text{CO})_3\text{Br}]\text{Br}$ (**4a**) and $[\text{Mo}(\text{PNP}-i\text{Pr})(\text{CO})_3\text{Br}]\text{Br}$ (**4b**), as illustrated in Scheme 3.

The solid-state structures of **3a** and **4b** were determined by single-crystal X-ray diffraction. Molecular views of **3a** and **4b** are depicted in Figures 1 and 2, respectively, with selected bond distances and angles reported in the captions. While the Mo-bonded bromide in **4b** was clearly in an axial position, the bromide in the tungsten complex **3a** adopted an axial position at about 86% occupancy ($\text{Br}1$ in Figure 1), while the remaining 14% exchanged places with the carbonyl group $\text{C}32\text{-O}3$.

Stirring complexes **3a–c** with an excess of 10% sodium amalgam in THF gave the desired W(0) complexes $[\text{W}(\text{PNP}-\text{Ph})(\text{CO})_3]$ (**5a**), $[\text{W}(\text{PNP}-i\text{Pr})(\text{CO})_3]$ (**5b**), and $[\text{W}(\text{PNP}-t\text{Bu})(\text{CO})_3]$ (**5c**) as yellow solids in 70–80% isolated yields (Scheme 3). This methodology also yields the analogous Mo(0) complexes thus being an alternative method to that described previously.¹³ The use of Zn as reducing reagent turned out to be problematic, due to the formation of highly soluble and, thus, difficult to remove bromozincate anions, e.g., $[\text{ZnBr}_3\text{-solvent}]^-$ (solvent = acetone, THF) and ZnBr_4^{2-} . Complexes **5a–c** were fully characterized by a combination of ^1H , $^{13}\text{C}\{^1\text{H}\}$, and $^{31}\text{P}\{^1\text{H}\}$ NMR spectroscopy, IR spectroscopy, and elemental analysis. Characteristic features of **5a–c** comprise, in the $^{13}\text{C}\{^1\text{H}\}$ NMR spectrum, two low-field triplet resonances (1/2 ratio) in the ranges of 206–221 and 196–210 ppm assignable to the carbonyl carbon atoms *trans* and *cis* to the pyridine nitrogen, respectively. The $^{31}\text{P}\{^1\text{H}\}$ NMR spectra exhibit singlet resonances at 85.2, 106.6, and 131.6 ppm with $^1J_{\text{WP}}$ coupling constants of 315–329 Hz. The tungsten–phosphorus coupling was observed as a doublet satellite due to ^{183}W , 14% abundance with $I = 1/2$, superimposed over the dominant singlet. The IR spectra show the typical three strong to medium absorption bands of a *mer* CO arrangement in the range of 2017–1760 cm^{-1} assignable to one weaker symmetric and two strong asymmetric ν_{CO} stretching modes. The ν_{CO} frequencies, in particular the symmetric CO stretch, is indicative of the increasing electron donor strengths of the PNP ligands and follow the order $\text{PNP}-\text{Ph} < \text{PNP}-i\text{Pr} \approx \text{PNP}^{\text{Me}}-i\text{Pr} < \text{PNP}-t\text{Bu}$ (Table 1). The CO stretching frequencies are 1964 (**2a**, PNP-Ph), 1936 (**2b**, PNP-*i*Pr), 1936 (**2d**, $\text{PNP}^{\text{Me}}-i\text{Pr}$), and 1922 cm^{-1} (**2c**, PNP-*t*Bu). The same order is found for the respective tungsten complexes. In all complexes the PNP pincer ligand adopts the typical *mer* coordination mode with no evidence for any *fac* isomers.²²

In addition to the spectroscopic characterization, the solid-state structures of **2d** and **5b,c** were determined by single-crystal X-ray diffraction. Structural views are depicted in Figures 3–5, respectively, with selected bond distances and angles given in the captions. The coordination geometry around the tungsten center of **5b,c** corresponds to a distorted octahedron with $\text{P}1\text{-W-P}2$ and *trans*- $\text{C}_{\text{CO}}\text{-W-C}_{\text{CO}}$ bond angles 154.43(4) and 165.7(2)° (**5b**), and 151.42(1) and 156.46(9)° (**5c**), respectively. For comparison, in the analogous

Scheme 3

Figure 1. Structural view of $[\text{W}(\text{PNP-Ph})(\text{CO})_3\text{Br}]\text{Br}\cdot\text{CH}_3\text{OH}$ ($3\text{a}\cdot\text{CH}_3\text{OH}$) showing 20% thermal ellipsoids (H atoms, Br^- counterion, solvent molecule and subordinate Br/CO positions omitted for clarity). Selected bond lengths (Å) and bond angles (deg): W–C(31) = 2.017(5), W–C(30) = 2.020(6), W–C(32) = 2.024(8), W–N(1) = 2.237(3), W–P(1) = 2.4955(10), W–P(2) = 2.4895(11), W–Br(1) = 2.6015(5); P(1)–W–P(2) = 152.34(4), N(1)–W–P(1) = 77.44(9), N(1)–W–P(2) = 75.92(9), N(1)–W–C(30) = 137.76(16), N(1)–W–C(31) = 82.35(16), N(1)–W–C(32) = 150.87(8), N(1)–W–Br(1) = 82.28(9).

$[\text{Mo}(\text{PNP})(\text{CO})_3]$ complexes **2a–d** the P1–Mo–P2 angles are hardly affected by the size of the substituents of the phosphorus atoms, being 155.0(2), 155.62(1), 155.3(1), and 151.73(1)°, respectively.^{12,13} The carbonyl–Mo–carbonyl angles of the CO ligands *trans* to one another, on the other hand, vary strongly with the bulkiness of the PR_2 moiety (PNP-Ph₂ < PNP-*i*Pr₂ < PNP^{Me}-*i*Pr < PNP-*t*Bu₂) and decrease from 171.1(8)° in $[\text{Mo}(\text{PNP-Ph})(\text{CO})_3]$, to 166.03(5)° in $[\text{Mo}(\text{PNP-}i\text{Pr})(\text{CO})_3]$, to 162.93(7)° in $[\text{Mo}(\text{PNP}^{\text{Me}}-i\text{Pr})(\text{CO})_3]$, and finally to 156.53(4)° in $[\text{Mo}(\text{PNP-}t\text{Bu})(\text{CO})_3]$.

Molybdenum(II) and Tungsten(II) Hydride Complexes. Addition of HBF_4 to a CH_2Cl_2 solution of $[\text{Mo}(\text{PNP})(\text{CO})_3]$ (**2a–d**) and $[\text{W}(\text{PNP})(\text{CO})_3]$ (**5a–c**) resulted in an immediate color change from yellow to pale yellow consistent with protonation at the tungsten and molybdenum centers to generate tungsten(II) and molybdenum(II) hydride complexes $[\text{Mo}(\text{PNP})(\text{CO})_3\text{H}]\text{BF}_4$ (**7a–d**) and $[\text{W}(\text{PNP})-$

Figure 2. Structural view of $[\text{Mo}(\text{PNP-}i\text{Pr})(\text{CO})_3\text{Br}]\text{Br}$ (**4b**) showing 50% thermal ellipsoids (Br^- counterion omitted for clarity). quantitatively (Scheme 4). All hydride complexes are thermally robust pale yellow solids that are air stable in the solid state but slowly decompose in solution. Characterization was accomplished by elemental analysis and by ^1H , $^{13}\text{C}\{^1\text{H}\}$, and $^{31}\text{P}\{^1\text{H}\}$ NMR and IR spectroscopy (Table 1). The recording of a $^{13}\text{C}\{^1\text{H}\}$ NMR spectrum of **8c** was precluded due to the poor solubility of this complex in most common solvents.

Seven-coordinate complexes are well-known for their fluxional behavior in solution,^{23,24} since typically none of the idealized geometries such as capped prism, capped octahedron, and pentagonal bipyramid or any of the less symmetrical

Figure 5. Structural view of $[\text{W}(\text{PNP-}t\text{Bu})(\text{CO})_3] \cdot \text{THF}$ (**5c**·THF) showing 50% thermal ellipsoids (H atoms and solvent molecule omitted for clarity). Scheme 4

arrangements are typically characterized by a markedly lower total energy.²⁵ Hence, interconversions between these various structures are quite facile. The fluxional behavior of complexes **7a–d** and **8a–c** was evident in variable-temperature ^1H and $^{31}\text{P}\{^1\text{H}\}$ NMR spectra. At room temperature, the ^1H NMR spectrum of complexes **7** and **8** confirmed the presence of one hydride ligand, which appeared in the range of -3.89 to -5.36 ppm either as a well-resolved doublet of doublets (**8b,c**) or as triplets (**7a–d**, **8a**).

At -60 °C, all hydride resonances appear as a well-resolved doublet of doublets with one large and one small coupling constant of about 21–36 and 47–53 Hz, respectively. As an example, the variable-temperature 300 MHz ^1H NMR spectra of the hydride region of $[\text{Mo}(\text{PNP-Ph})(\text{CO})_3\text{H}]\text{BF}_4$ (**7a**) are shown in Figure 6. At low temperatures the hydride signal constitutes the X part of an AMX spin system, giving rise to a doublet of doublets which, at elevated temperatures in the fast exchange regime, becomes a simple A_2X spin system where the X part exhibits a triplet resonance.

In the $^{13}\text{C}\{^1\text{H}\}$ NMR spectrum of complexes **7a–d** and **8a–d** the most noticeable resonances are two low-field resonances of the carbonyl carbon atoms *trans* and *cis* to the pyridine nitrogen observed as two triplets in a 1:2 ratio. At room temperature, no $^{31}\text{P}\{^1\text{H}\}$ NMR signals could be detected for molybdenum complexes **7a–d** and the tungsten complex **8a** due to their fluxional behavior. At -60 °C, however, the $^{31}\text{P}\{^1\text{H}\}$ NMR spectra of all complexes **8** give rise to two doublets with a large geminal coupling constant of about 80 Hz, which is indicative of the phosphorus atoms being in mutually *trans* positions. The IR spectra of **7** and **8** show three strong to

Figure 6. Variable-temperature 300 MHz ^1H NMR spectra of the hydride region of $[\text{Mo}(\text{PNP-Ph})(\text{CO})_3\text{H}]\text{BF}_4$ (**7a**) in CD_2Cl_2 .

medium absorption ν_{CO} bands of the one symmetric and the two asymmetric vibration modes (Table 1), which again are typical for a *mer* CO arrangement.

In addition to the spectroscopic characterization, the solid-state structures of **7a,d** and **8a** were determined by single-crystal X-ray diffraction. Structural diagrams are depicted in Figures 7–9, respectively, with selected bond distances given in

Figure 7. Structural view of $[\text{Mo}(\text{PNP-Ph})(\text{CO})_3\text{H}]\text{BF}_4$ (**7a**) showing 50% thermal ellipsoids (BF_4^- counterion and alternative orientation of $\text{C}(32)\text{-O}(3)$ and $\text{H}(1)$ omitted for clarity). Selected bond lengths (\AA) and bond angles (deg): $\text{Mo-H}(1) = 1.63(2)$, $\text{Mo-C}(20) = 2.0440(13)$, $\text{Mo-C}(21) = 2.0239(13)$, $\text{Mo-C}(22) = 1.9856(13)$, $\text{Mo-N}(1) = 2.2462(10)$, $\text{Mo-P}(1) = 2.4425(3)$, $\text{Mo-P}(2) = 2.4776(3)$; $\text{P}(1)\text{-Mo-P}(2) = 154.61(1)$, $\text{N}(1)\text{-Mo-P}(1) = 77.29(3)$, $\text{N}(1)\text{-Mo-P}(2) = 77.31(3)$, $\text{N}(1)\text{-Mo-C}(20) = 94.27(4)$, $\text{N}(1)\text{-Mo-C}(21) = 89.76(4)$, $\text{N}(1)\text{-Mo-C}(22) = 162.26(4)$, $\text{N}(1)\text{-Mo-H}(1) = 145.7(8)$, $\text{C}(22)\text{-Mo-H}(1) = 52.0(8)$.

Figure 9. Structural view of $[\text{W}(\text{PNP-Ph})(\text{CO})_3\text{H}]\text{BF}_4$ (**8a**) showing 50% thermal ellipsoids (BF_4^- counterion and alternative orientation of $\text{C}(32)\text{-O}(3)$ and $\text{H}(1)$ omitted for clarity). Selected bond lengths (\AA) and bond angles (deg): $\text{W-H}(1) = 1.65(5)$, $\text{W-C}(30) = 2.033(2)$, $\text{W-C}(31) = 2.039(2)$, $\text{W-C}(32) = 2.022(4)$, $\text{W-N}(1) = 2.2316(15)$, $\text{W-P}(1) = 2.4444(5)$, $\text{W-P}(2) = 2.4459(5)$; $\text{P}(1)\text{-W-P}(2) = 154.32(2)$, $\text{N}(1)\text{-W-P}(1) = 77.17(4)$, $\text{N}(1)\text{-W-P}(2) = 77.29(4)$, $\text{N}(1)\text{-W-C}(30) = 87.78(7)$, $\text{N}(1)\text{-W-C}(31) = 86.88(7)$, $\text{N}(1)\text{-W-C}(32) = 162.35(11)$, $\text{N}(1)\text{-W-H}(1) = 143.5(17)$, $\text{C}(32)\text{-W-H}(1) = 53.9(17)$.

hydride bond length in the three complexes averages 1.65 \AA (1.64–1.70 \AA), the mean bond angle H-M-P to the nearest P atom is 67° ($65\text{--}69^\circ$), and the mean bond angle H-M-C between hydride and the equatorial carbonyl group is 53° ($50\text{--}55^\circ$). The hydride to carbonyl C atom distance (1.62 \AA in **7d**) and the almost linear attachment of the equatorial carbonyl group ($\text{Mo1-C22-O3} = 179^\circ$ in **7d**) do not indicate a significant bonding interaction between hydride and the adjacent carbonyl C atom in the three structurally characterized hydrido carbonyl complexes.

The mechanism of the dynamic process of the hydrido carbonyl complexes was investigated by means of DFT

calculations²⁶ for the molybdenum and tungsten complexes $[\text{Mo}(\text{PNP})(\text{CO})_3\text{H}]^+$ (7a–c) and $[\text{W}(\text{PNP})(\text{CO})_3\text{H}]^+$ (8a–c). The free energy profile for the “pseudorotation” is depicted in Figure 10. The optimized structures of 8a,c and the

Figure 10. Free energy profile (in kcal/mol) for the “pseudorotation” of CO and hydride ligands in the complexes $[\text{M}(\text{PNP})(\text{CO})_3\text{H}]^+$ (M = W, Mo).

Figure 11. Front (left) and side views (right) of the optimized structures (DFT/B3LYP) of the tungsten complex $[\text{W}(\text{PNP-Ph})(\text{CO})_3\text{H}]^+$ (8a; top) and the transition state TS (bottom) with most phenyl carbon atoms and hydrogen atoms omitted for clarity.

corresponding transition states TS are shown in Figures 11 and 12. In the fluxional process, the CO and the hydride ligands in the PNP plane exchange positions in a single-step path. During that process the rest of the molecule has to change in order to accommodate the overall transformations associated with the pseudorotation. The main geometry change that happens along the path is the hydride ligand moving from the PNP plane to the perpendicular plane, i.e., the plane of the three CO ligands, in the transition state (TS) and then back to the PNP plane again but on the other side of the CO ligand. Thus, in TS, the two *trans* CO ligands have to create enough space to allow the presence of an extra ligand in the NCCC plane, opening the corresponding OC–M–CO angle and bending away from the

Figure 12. Front (left) and side views (right) of the optimized structures (DFT/B3LYP) of the tungsten complex $[\text{W}(\text{PNP-}t\text{Bu})(\text{CO})_3\text{H}]^+$ (8c; top) and the transition state TS (bottom) with most *t*Bu carbon atoms and hydrogen atoms omitted for clarity.

hydride ligand. Accordingly, in the case of the molybdenum and tungsten PNP complexes bearing the less bulky Ph and *i*Pr substituents (7a,b and 8a,b), the C30–W1–C31 angle changes from about 177° in the ground-state structure to 166° in TS, where both *trans* CO ligands are bent toward the PNP ligand (Figure 11). On the other hand, in the case of the molybdenum and tungsten PNP complexes bearing the bulky *t*Bu substituents (7c and 8c) the situation is somewhat different. The C30–W1–C31 angle increases from 169° in the minima to 178° in TS, while one of the two *trans* CO ligands is severely bent away from the PNP ligand and the other one is bent toward the PNP ligand (Figure 12). In the course of all these transformations also the H1–W1–C32 angles change from about 55° in 7a–c and 8a–c to roughly 43° in the TS, respectively. Bond distances are hardly affected by the interconversion. It is interesting to note that, in agreement with the X-ray structures of 7a, 7d, and 8a (Figures 6–8), the distance between H1 and C32 is rather short, being in the range of 1.80–1.66 Å. A Wiberg index²⁷ of 0.20, in 8c, seems to indicate an attractive interaction between the hydride and the neighboring C_{CO} atom (C32). Most importantly, the free energy barriers ΔG^\ddagger are 18.6 and 21.3 kcal/mol for 7c and 8c, respectively, containing the bulky *t*Bu substituents. In the case of all other complexes the free energy barrier is lower, being in the range of 12.5–16.1 kcal/mol, as shown in Figure 9. These results corroborate a process that can be stopped in the temperature range employed in the NMR studies and a more facile process in the case of the Mo species, as observed.

CONCLUSION

In the present study the Mo(0) and W(0) complexes $[\text{M}(\text{PNP})\text{CO}_3]$ as well as seven-coordinate cationic hydrido carbonyl and halo carbonyl Mo(II) and W(II) complexes of the type $[\text{M}(\text{PNP})(\text{CO})_3\text{Br}]^+$ and $[\text{M}(\text{PNP})(\text{CO})_3\text{H}]^+$ featuring PNP pincer ligands based on 2,6-diaminopyridine were prepared and fully characterized. The synthesis of the Mo(0) complexes $[\text{Mo}(\text{PNP})\text{CO}_3]$ was accomplished by treatment of $[\text{Mo}(\text{CO})_3(\text{CH}_3\text{CN})_3]$ with the respective PNP ligands. The analogous W(0) complexes were prepared by reduction of the bromo carbonyl complexes $[\text{W}(\text{PNP})(\text{CO})_3\text{Br}]^+$ with NaHg. These intermediates were obtained from the known dinuclear complex $[\text{W}(\text{CO})_4(\mu\text{-Br})\text{Br}]_2$, prepared in situ from $\text{W}(\text{CO})_6$ and stoichiometric amounts of Br_2 . Addition of HBF_4 to $[\text{M}(\text{PNP})(\text{CO})_3]$ resulted in protonation at the tungsten and

molybdenum centers to formally generate the Mo(II) and W(II) hydride complexes $[M(\text{PNP})(\text{CO})_3\text{H}]^+$. The protonation is fully reversible, and upon addition of NEt_3 as base the Mo(0) and W(0) complexes $[M(\text{PNP})(\text{CO})_3]$ are re-formed quantitatively. All seven-coordinate complexes exhibit fluxional behavior in solution, since none of the idealized geometries (capped prism, capped octahedron, and pentagonal bipyramid) or any of the less symmetrical arrangements are typically characterized by a markedly lower total energy. The mechanism of the dynamic process of the hydrido carbonyl complexes was investigated by means of DFT calculations, revealing that it occurs in a single step. Thereby the CO and the hydride ligands which are situated in the PNP plane are interconverted. The structures of representative complexes were determined by X-ray single-crystal analyses.

EXPERIMENTAL SECTION

General Considerations. All manipulations were performed under an inert atmosphere of argon by using Schlenk techniques. The solvents were purified according to standard procedures.²⁸ The ligands and complexes *N,N'*-bis(diphenylphosphino)-2,6-diaminopyridine (PNP-Ph; **1a**), *N,N'*-bis(diisopropylphosphino)-2,6-diaminopyridine (PNP-*i*Pr; **1b**), *N,N'*-bis(di-*tert*-butylphosphino)-2,6-diaminopyridine (PNP-*t*Bu; **1c**), $[\text{Mo}(\text{PNP-Ph})(\text{CO})_3]$ (**2a**), $[\text{Mo}(\text{PNP-}i\text{Pr})(\text{CO})_3]$ (**2b**), and $[\text{Mo}(\text{PNP-}t\text{Bu})(\text{CO})_3]$ (**2c**) were prepared according to the literature.¹³ The deuterated solvents were purchased from Aldrich and dried over 4 Å molecular sieves. ^1H , $^{13}\text{C}\{^1\text{H}\}$, and $^{31}\text{P}\{^1\text{H}\}$ NMR spectra were recorded on Bruker AVANCE-250 and AVANCE-300 DPX spectrometers and were referenced to SiMe_4 and H_3PO_4 (85%), respectively.

***N,N'*-Bis(diisopropylphosphino-borane)-2,6-diaminopyridine (PNP-*i*Pr; **1b**·BH₃).** BH₃·THF (43.1 mL, 1.0 M, 43.06 mmol) was added slowly to a solution of **1b** (7.00 g, 20.50 mmol) in 100 mL of dry THF. After the mixture was stirred for 30 min at room temperature, the solvent was evaporated under reduced pressure. The white solid was further dried under vacuum for 2 h to give the product in quantitative yield. Anal. Calcd for $\text{C}_{17}\text{H}_{39}\text{B}_2\text{N}_3\text{P}_2$: C, 55.32; H, 10.65; N, 11.39. Found: C, 55.28; H, 10.70; N, 11.43. ^1H NMR (δ , CDCl₃, 20 °C): 7.32 (t, $J = 7.9$ Hz, 1H, py⁴), 6.26 (d, $J = 7.9$, 2H, py^{3,5}), 4.58 (d, $J = 8.4$ Hz, 2H, NH), 2.62 (septd, $J = 6.9$ Hz, $J = 13.7$ Hz, 4H, CH(CH₃)₂), 1.16 (m, 24H, CH(CH₃)₂), 0.60 to -0.15 (bs, 6H, BH₃). $^{13}\text{C}\{^1\text{H}\}$ NMR (δ , CDCl₃, 20 °C): 154.4 (s, py^{2,6}), 140.1 (s, py⁴), 103.1 (s, py^{3,5}), 24.5 (d, $J = 36.3$ Hz, CH(CH₃)₂), 17.2 (d, $J = 4.3$ Hz, CH(CH₃)₂), 17.0 (s, CH(CH₃)₂). $^{31}\text{P}\{^1\text{H}\}$ NMR (δ , CDCl₃, 20 °C): 88.5 (br, m).

***N,N'*-Bis(diisopropylphosphino-borane)-*N,N'*-methyl-2,6-diaminopyridine (PNP^{Me}-*i*Pr; **1d**·BH₃).** To a solution of **1b**·BH₃ (7.45 g, 20.19 mmol) in THF (50 mL) at -20 °C was slowly added *n*-BuLi (17.0 mL, 2.5 M, 41.39 mmol). The reaction mixture was allowed to reach room temperature and was stirred for 2 h. Methyl iodide (3.15 mL, 50.46 mmol) was then added slowly via syringe. After the mixture was stirred for 12 h at room temperature, the reaction was quenched with a saturated NH₄Cl solution (100 mL) and 5 mL of concentrated NH₃. The aqueous phase was extracted twice with CH₂Cl₂, and the combined organic phases were washed with 25 mL of brine and dried over Na₂SO₄. The solvent was removed under reduced pressure to afford **1d**·BH₃ as a yellow oil. The crude product was purified via flash chromatography using silica gel and THF to give the product as a white solid. Anal. Calcd for $\text{C}_{19}\text{H}_{43}\text{B}_2\text{N}_3\text{P}_2$: C, 57.56; H, 10.91; N, 10.58. Found: C, 57.62; H, 10.89; N, 10.61. X-ray Structure Determination. Single crystals of the complexes 3a, 4b, 2d, 5b,c, 7a,d, and 8a suitable for X-ray diffraction were mainly obtained by the solvent/antisolvent liquid–liquid diffusion method at room temperature using CH₂Cl₂/diethyl ether (4b, 2d, 7a,d, 8a) or THF/*n*-hexane (5b,c), while 3a was crystallized from methanol at -20 °C. The crystals of 3a, 5b,c, and 7d were solvates (3a·CH₃OH, 5b·THF·¹/₂hexane, 5c·THF, 7d·CH₂Cl₂). X-ray diffraction data were collected at *T* = 100 K on a Bruker Kappa APEX-2 CCD area detector diffractometer using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å) and φ - and ω -scan frames covering complete spheres of the reciprocal space with θ_{\max} = 30°. Corrections for absorption and $\lambda/2$ effects were applied using the program SADABS.²⁹ After structure solution with the program SHELXS97 refinement on *F*² was carried out with the program SHELXL97.³⁰ Non-hydrogen atoms were refined anisotropically. Most hydrogen atoms were placed in calculated positions and thereafter treated as riding. Crystal data are reported in Table 2, and detailed structural data are given in CIF format in the Supporting Information. Variants are as follows. The solid-state structure of 3a (3a·CH₃OH) contained methanol and eventually some water disordered in a large oval infinite channel along the *a* axis embodying also the free bromide anions. The contribution of this solvent to the structure factors was removed with the procedure SQUEEZE of the program PLATON.³¹ This structure shows also a Br by CO and a complementary CO by Br substitution disorder (equatorial C32–O3 by Br1' and axial Br1 by C32' and O3' in 86:14 proportion). The crystal structure of 5b contains an ordered THF and a disordered *n*-hexane solvent molecule, the latter across a center of inversion; the solid is therefore 5b·THF·¹/₂C₆H₁₄. The contribution of the *n*-hexane solvent molecule to the structure factors was removed

with the procedure SQUEEZE of the program PLATON. 5b has also an orientation-disordered isopropyl group. The hydride complexes 7a and 8a form an isostructural pair, [Mo/W(PNP-Ph)(CO)₃H]BF₄, space group *Pbca*, with very similar unit cell dimensions, bond lengths, and bond angles. Both structures show a disorder of the equatorial CO group (C32–O3) and the hydride H atom (H1), which appear in two approximately equivalent positions left and right of the plane bisecting the complexes perpendicular to the pyridine ring. Due to the very good quality of the diffraction data of both complexes and due to good separations of the respective atom positions, it was possible to refine the approximately half-occupied positions of the hydride H atoms without restraints. The left/right ratio of the population parameter of CO and H in the molybdenum complex 7a is 0.540(3)/0.460(3) and in the tungsten complex 8a is 0.586(4)/0.414(4) (for C32, O3, H1/C32', O3', H1'; cf. Figures 7 and 9, which depict only the dominant nonprimed part). In contrast, the analogous molybdenum hydrido carbonyl complex 7d·CH₂Cl₂ was perfectly ordered and gave on refinement with high-quality diffraction data a hydride position in very good agreement with complexes 7a and 8a, fully supporting the split atom refinements of these two crystal structures.

Computational Details. All calculations were performed using the GAUSSIAN 09 software package³² on the Phoenix Linux Cluster of the Vienna University of Technology and the B3LYP functional³³ without symmetry constraints. The optimized geometries were obtained with the Stuttgart/Dresden ECP (SDD) basis set³⁴ to describe the electrons of the tungsten and molybdenum atoms. For all other atoms a standard 6-31g** basis set was employed.³⁵ All geometries were optimized without symmetry constraints. Frequency calculations were performed to confirm the nature of the stationary points, yielding one imaginary frequency for the transition states and none for the minima. Each transition state was further confirmed by following its vibrational mode downhill on both sides and obtaining the minima presented on the energy profiles. All energies reported are Gibbs free energies and thus contain zero-point, thermal, and entropy effects at 298 K and 1 atm pressure. A natural population analysis (NPA)³⁶ and the resulting Wiberg indices²⁷ were used to study the electronic structure and bonding of the optimized species. The NPA analysis was performed with the NBO 5.0 program.³⁷
